22 **Abstract**

23 Widespread vulture population declines are often counteracted by conservation

24 strategies including reintroduction programs and supplementary feeding schemes.

25 However, the role of supplementary feeding – focusing on specific, predictable,

26 feeding sites - on movement behaviour, has been little explored, especially within

27 populations in which reintroduced and wild born birds of different age-classes may

28 show differing behavioural movement patterns. However, such information becomes

29 crucial for improving conservation and management actions. We analysed GPS data  
30 from both reintroduced (n = 31) and wild born (n = 28) cinereous vultures *Aegypius*  
31 *monachus* in Catalonia, North-eastern Spain, collected during a long-term study  
32 (2009–2020), to assess SFS use patterns according to natal origin, release method,  
33 and age-classes of individuals. We found high age-related variation in SFS use;  
34 juveniles revisited fewer SFS, and spent much longer in these locations compared  
35 with immatures, subadults, and adults, pointing to a dependence of juveniles on social  
36 information, along with a lack of foraging and flight skills. Regular adult revisits to  
37 multiple SFS suggests that these vultures can develop a comprehensive spatial  
38 memory of SFS by adulthood. Additionally, birds that were released via an  
39 acclimatisation aviary showed lower affiliation with SFS compared with ‘hacked’ birds  
40 and wild-born nestlings perhaps suggesting a tendency to spend more time exploring  
41 the wider environment. Our study has particular relevance in light of the potential  
42 public health-related legislation changes within the European Union or the changes in  
43 management of SFS, which could alter movement patterns and demographic  
44 parameters of Iberian vulture populations.

## 48 Introduction

49 Anthropogenic activities are among the major drivers of the global decline in  
50 avian scavenger populations (Safford *et al.*, 2019; Harfoot *et al.*, 2021). Key threats  
51 include illegal persecution (Margalida, Ogada and Botha, 2019), accidental poisoning  
52 (Berny *et al.*, 2015, Oliva-Vidal *et al.* 2022), and collision with anthropogenic  
53 infrastructure (Carrete *et al.*, 2009; Ives *et al.*, 2022). Conservation actions such as  
54 captive breeding and reintroduction programs, have to some extent mitigated these  
55 population declines (Lorand *et al.*, 2025). In combination with the establishment and  
56 provision of foraging resources through supplementary feeding sites (SFS) (Moreno-  
57 Opo, Trujillano and Margalida, 2015; Cortés-Avizanda *et al.*, 2016),

58 Populations of certain vulture species (Margalida and Colomer, 2012), as well  
59 as other bird species e.g., white storks *Ciconia Ciconia* (López-García and Aguirre,  
60 2023), have become heavily reliant on predictable, human-modified resources,  
61 including landfill sites (Monsarrat *et al.*, 2013; Tauler-Ametller *et al.*, 2017; Cortés-  
62 Avizanda *et al.*, 2025). As a result, the spatial distribution, movement patterns, and  
63 home-range dynamics of these scavengers are therefore strongly influenced by the  
64 location, quality, and temporal stability of such anthropogenic resources (López-  
65 López *et al.* 2014, Margalida *et al.* 2016). However, some detrimental effects have  
66 been documented related to the use of supplementary feeding sites (SFS; Carrete *et*  
67 *al.* 2006, Cortés-Avizanda *et al.* 2016). Additionally, while predictable food resources  
68 generally increase foraging opportunities, it also promotes high-density aggregations  
69 that can exacerbate dominance hierarchies (Cortés-Avizanda, Carrete and Donázar,  
70 2010; Moreno-Opo, Trujillano and Margalida, 2020), and cause negative density-  
71 dependent effects on fecundity (Carrete, Donázar and Margalida, 2006), as well as

72 increasing the risk of disease and parasite transmission (Van Overveld, Gangoso, *et*  
73 *al.*, 2020).

74 Studies conducted on vulture species on the Iberian Peninsula have identified  
75 stratified age-related differences in the use of SFS. Juvenile foraging inefficiency is  
76 common across many species (Carmona, Aymí and Navarro, 2021), linked to  
77 inexperience in locating and competing for food resources (Fayet *et al.*, 2015). This  
78 means that although subdominant, non-breeding vultures prefer to exploit regularly  
79 stocked SFS, such as smaller, farm-based carcass deposition sites (Kane *et al.*,  
80 2016; Morant *et al.*, 2020), their actual access to available food resources such as  
81 carcasses remains restricted by competitive exclusion from dominant adults (Duriez,  
82 Herman and Sarrazin, 2012; Van Overveld *et al.*, 2018; Moreno-Opo, Trujillano and  
83 Margalida, 2020). For example, adult griffon vultures (*Gyps fulvus*) tend to form  
84 foraging groups at SFS located within short distances (5 -10km) of their breeding  
85 colonies (Zuberogoitia *et al.*, 2013a; Cerri *et al.*, 2023), causing higher density  
86 competition that may exclude juveniles from profitable sites.

87 Despite both intra- and interspecific competition for such resources, time  
88 spent at locations with predictable food resources is also likely used as a way to form  
89 social relationships and identify suitable future breeding areas particularly among  
90 juveniles (Van Overveld *et al.*, 2018; Van Overveld, Gangoso, *et al.*, 2020). Such  
91 opportunities of social information exchange fit with the Information Centre  
92 Hypothesis (Buckley, 1996; Harel *et al.*, 2017), which may be particularly relevant for  
93 reintroduced individuals.

94 Vulture reintroduction has proved highly successful in several areas of  
95 Europe, with populations of Griffon, Bearded and Cinereous vulture *Aegypius*

96 *monachus* translocated across Spain, France, Italy and Bulgaria primarily (Schaub *et*  
97 *al.*, 2009; Ivanov *et al.*, 2023; Monti *et al.*, 2023; Stoyanov *et al.*, 2023; Lorand *et al.*,  
98 2025). Although many breeding populations have become well established, there is  
99 a potential hindrance to population maintenance and expansion because birds that  
100 are released from captive breeding or rehabilitation centres come with limited social  
101 and foraging experience (Fozzi *et al.*, 2023). Amongst reintroduced vultures,  
102 acclimated individuals observe the release site and their conspecifics from an aviary  
103 (as opposed to 'hacked' individuals that are released into a nest whilst flightless;  
104 Mihoub *et al.*, 2014), and have shown improved breeding success and survival as  
105 adults, particularly those acclimated for a longer period of time, as they are able to  
106 form partial cognitive maps to help them locate foraging sites (Fozzi *et al.* 2023).  
107 Reintroduced individuals overall often display more erratic dispersal movements  
108 (Rousteau *et al.*, 2022; Tréhin *et al.*, 2024a), and show species-specific differences  
109 in home range size compared to wild-born birds (Rousteau *et al.* 2022, Fozzi *et al.*  
110 2023), both of which are likely to affect the dynamics of SFS use. Concentrating food  
111 resources in specific locations may unintentionally restrict juvenile dispersal among  
112 individuals and hinder population expansion (Margalida *et al.*, 2013; Cortés-Avizanda  
113 *et al.*, 2016; Reznikov *et al.*, 2024), and can also reduce the efficiency of vulture  
114 scavenging services throughout the wider landscape (Deygout *et al.*, 2009).

115 European sanitary regulations modified carcass availability and stocking  
116 densities at SFS, and in some cases led to their complete removal from the  
117 landscape (Margalida, Pérez-García and Moreno-Opo, 2017; Fernández-Gómez,  
118 Cortés-Avizanda, Arrondo, *et al.*, 2022). These changes altered resource  
119 distribution, and potentially population dynamics of both wild and reintroduced  
120 obligate scavengers (Cerecedo-Iglesias *et al.*, 2023; Colomer and Margalida, 2025).

121 Therefore, future legislation aiming to ‘clean up’ landscapes by closing open landfill  
122 sites and large carcass deposition sites has the potential to induce varying  
123 responses in productivity, survival, and alter the use patterns of remaining SFS  
124 (Zuberogoitia *et al.*, 2010; Cerecedo-Iglesias *et al.*, 2023). Empirical studies  
125 examining responses to site closures remain limited, but reveal declines in apparent  
126 survival, as well as changes in visit frequency and competitive behaviour  
127 (Zuberogoitia *et al.*, 2010; Margalida, Pérez-García and Moreno-Opo, 2017; Arévalo-  
128 Ayala *et al.*, 2023).

129 Collectively, these findings highlight how limited our understanding remains  
130 regarding the effects of SFS on vulture behaviour, including social associations and  
131 foraging strategies. A more comprehensive understanding of the dynamics of SFS  
132 use is needed to clarify how these sites support both reintroduced and wild vulture  
133 populations. Although vulture movement is well studied using bird-borne devices  
134 (Alarcón and Lambertucci, 2018), most GPS-based analyses have largely focused  
135 on estimation of metrics such as home range, or geometric information (Morant *et*  
136 *al.*, 2023; Tobajas *et al.*, 2024; Tréhin *et al.*, 2024a), rather than specific site use  
137 information, such as identifying which foraging locations are important to different  
138 groups of individuals (ages, origins), that could inform conservation prioritization and  
139 feeding site management regulation (Fernández-Gómez *et al.* 2022).

140 Here, we use GPS tracking data collected over a 12-year period in north-  
141 eastern Spain, to quantify use of SFS by both reintroduced and wild-born Cinereous  
142 vultures. Globally, while this species remains in decline, the Iberian Peninsula  
143 population has increased and is home of 90% of European population (Moreno-Opo  
144 & Margalida 2012; Terraube *et al.* 2012). Movement studies centred on Extremadura,  
145 Catalonia, and Aragón show that juveniles range farther than adults, especially

146 during the breeding season when adults are constrained by nesting (Moreno-Opo,  
147 Trujillano and Margalida, 2015; Tobajas *et al.*, 2024). However, detailed information  
148 on their use of SFSs and other discrete foraging areas is lacking. Here, we quantify  
149 revisitation to SFS within and between age groups. Release origins, sexes, years  
150 and months. Revisitation behaviour, i.e., the tendency to return to a previously visited  
151 location, is associated with animals that possess the capacity for spatial memory to  
152 exploit resources that deplete and renew predictably within a heterogeneous  
153 environment (Berger-Tal and Bar-David, 2015; Bracis *et al.*, 2015). Such behaviour  
154 can enable individuals to optimize foraging efficiency, reduce uncertainty, and  
155 enhance survival in dynamic landscapes.

156 Our study had two main objectives: 1) to identify patterns of use of specific,  
157 known SFS by Cinereous vultures; 2) to investigate variation in site-use metrics (time  
158 spent there, number of revisits) between age classes (birds born or released as  
159 juveniles, became immature (IMM) in their third calendar year, subadults (SUB) in  
160 their fourth, and full adults (FAD) in their fifth; and between wild-born and  
161 reintroduced individuals.

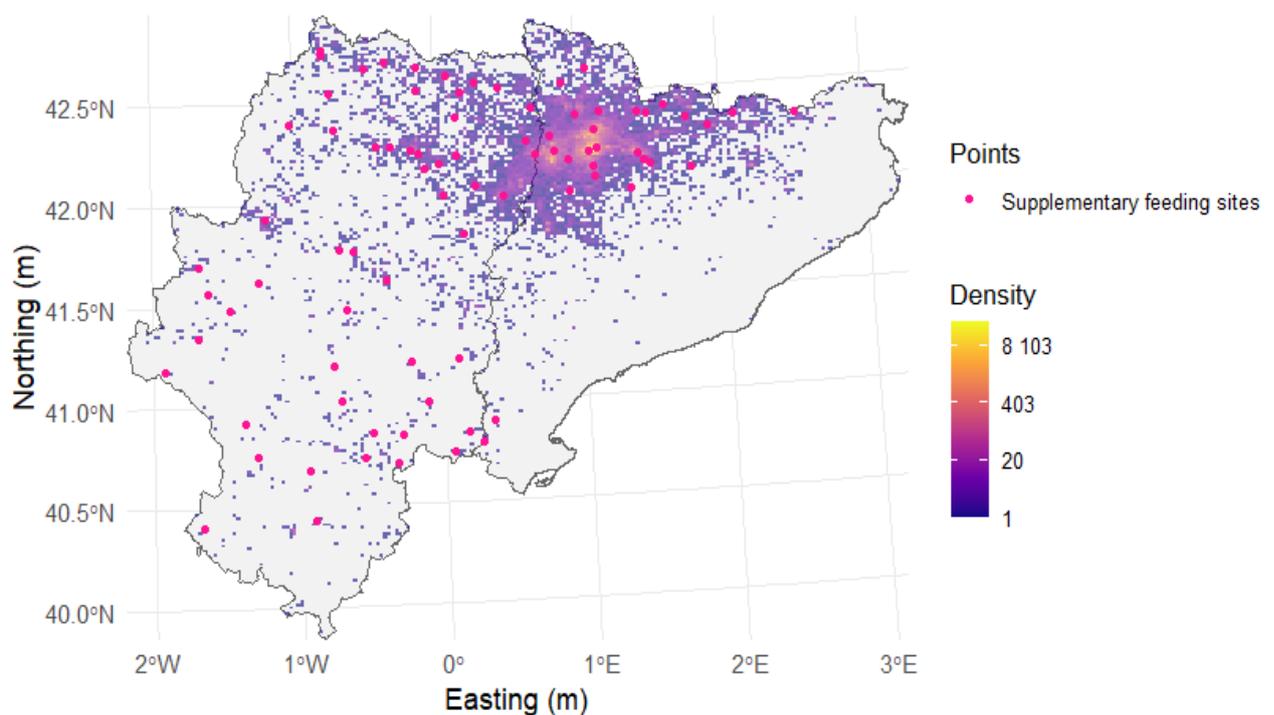

162

## 163 **Materials and methods**

### 164 *Tracking and data collection*

165 We obtained GPS tracking data from 73 Cinereous vultures collected in  
166 Catalonia (NE Spain; Figure 1) between 2009-2020 (Supp Mat), all of which accrued  
167 more than 100 days tracked [113 – 4243 days]. Each bird was categorised as either  
168 'wild born', 'hacked', or 'acclimated', and was molecularly sexed (Wink *et al.* 1998).  
169 The individuals were tagged as part of the project to recover the cinereous vulture in

170 the Pyrenees managed by Catalan government and Grupo de Rehabilitación de la  
171 Fauna Autóctona y su Hábitat (GREFA). All cinereous vultures were classified into  
172 four age-classes based on plumage characteristics following Clark (2004) and De la  
173 Puente and Elorriaga (2012). Within the dataset, birds could age during the tracking  
174 period; we therefore applied a universal threshold date of 15 March, chosen to align  
175 with egg hatching, after which individuals were incremented in age (Ruby, Kumar  
176 and Kanaujia, 2018).

177

178 Figure 1: Density of GPS points from n = 59 Cinereous vultures per 2 km across Catalonia and  
179 Aragón, north-eastern Spain, from 2009 to 2020. Pink points represent Supplementary Feeding  
180 Sites (SFS).

181 Tracking data were categorised by season as follows; Spring: March – May,  
182 summer: June - August, autumn: September – November, winter: December –  
183 February. Phenologically, spring and summer correspond to the incubation and  
184 rearing period. Autumn and winter correspond to the post-fledging and pre-laying

185 period. To ensure comparability among individuals with differing sampling intervals,  
186 the dataset was subsampled to retain one GPS location every four hours.

187

### 188 *Revisitation analysis*

189 After filtering the data, we conducted revisitation analysis on known feeding  
190 sites (SFS and landfills) using the package *recurse* (v. 1.4.0; Bracis et al. 2018) in R  
191 (v. 4.4.2). In order to understand how frequently SFS were revisited and whether this  
192 varied among different ages and origins, each SFS location was buffered at a  
193 biologically relevant distance; specifically, a 1 km buffer was applied to point  
194 locations of SFS and landfills across Spain (Monsarrat et al. 2013). This distance  
195 represents the approximate visual detection range from which vultures are able to  
196 see conspecifics circling in the sky, and thus become aware of a potential carcass or  
197 feeding opportunity, drawing them to that location (Jackson et al. 2008).

198 Revisits were defined as repeated visits to a specific SFS, having first exited  
199 the 1km boundary. In addition to quantifying the number of revisits to a given feeding  
200 site, the time spent at each feeding site was calculated using the function  
201 *getRecursionsAtLocations*. These metrics were then summarized across sites and  
202 individuals, and further aggregated by year and season, to describe the visitation  
203 patterns and the number of feeding sites visited in relation to age classes and origin.

### 204 *Data analysis*

205 Following filtering of individuals represented by only a single occurrence in the  
206 summarised dataset, and outliers in time spent at sites, the final dataset comprised  
207 59 individuals. To examine variation in use of sites among age classes and release  
208 origins, we fitted three generalised linear mixed models (GLMMs).

209 Individual identity was included as a random effect, with observations grouped  
210 by year, to account for repeated measures across years. We tested for differences in  
211 the number of SFS visited using a Poisson error distribution; in the number of revisits  
212 to SFS using a negative binomial distribution; and in mean time spent at each  
213 revisited location (i.e. > one single visit) using a Gaussian distribution applied to log-  
214 transformed data. The fixed effects included season (as defined above), the number  
215 of days each individual was tracked per season, year, sex, calendar age, and origin  
216 (hacked, acclimated, or wild). Where model diagnostics indicated heteroscedasticity  
217 across years and season, we incorporated one or more dispersion parameters to  
218 improve model fit. For the gaussian model we report estimates and confidence  
219 intervals in the text; for the Poisson and negative binomial models we report  
220 incidence rate ratios and their confidence intervals (Brooks *et al.*, 2017). Full model  
221 output tables are available in the supplementary information.

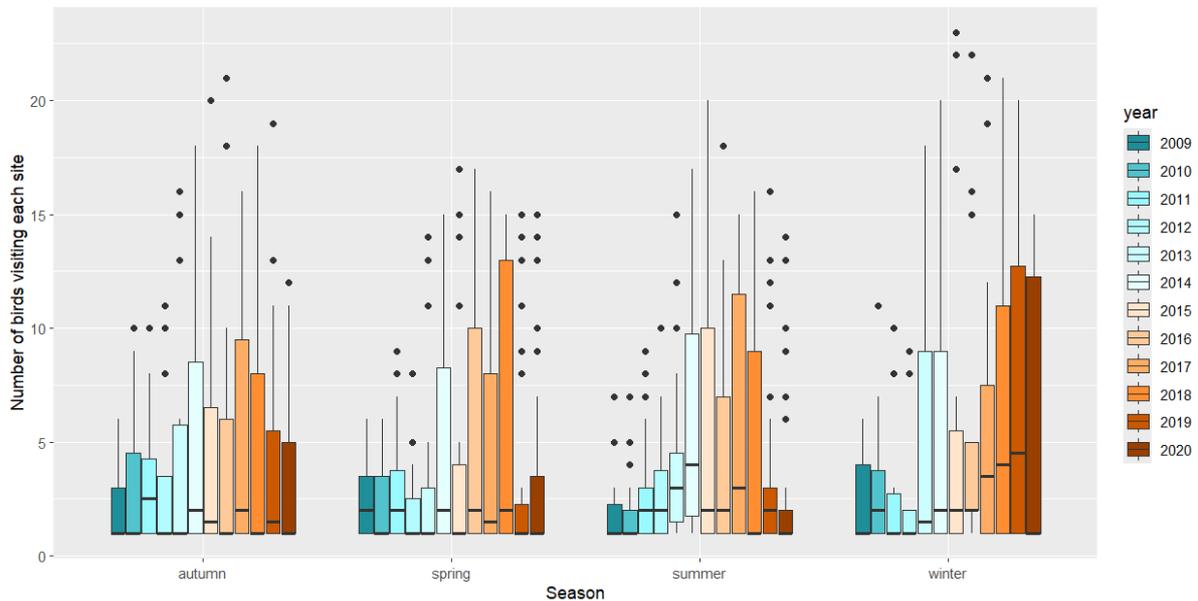

222

## 223 Results

### 224 *Overall use of supplementary feeding sites*

225 There were 89 distinct feeding sites, all of which were SFS (not landfills), that  
226 were revisited during the 12-year tracking period (Figure 1). The most frequently  
227 revisited feeding sites were closely associated with the colony and release site  
228 (within 10 km). SFS were visited by an average of 5.8 (+/- se. 0.22 birds), although  
229 this mean was biased by the maximum of 23 birds, and many sites (per month and  
230 year) that were only visited by one bird. The number of vultures using the SFSs was  
231 also higher in winter (mean: 6.6 birds +/- se. 0.61), particularly compared to summer

232 (mean: 5.3 +/- se. 0.37; figure 2).

233

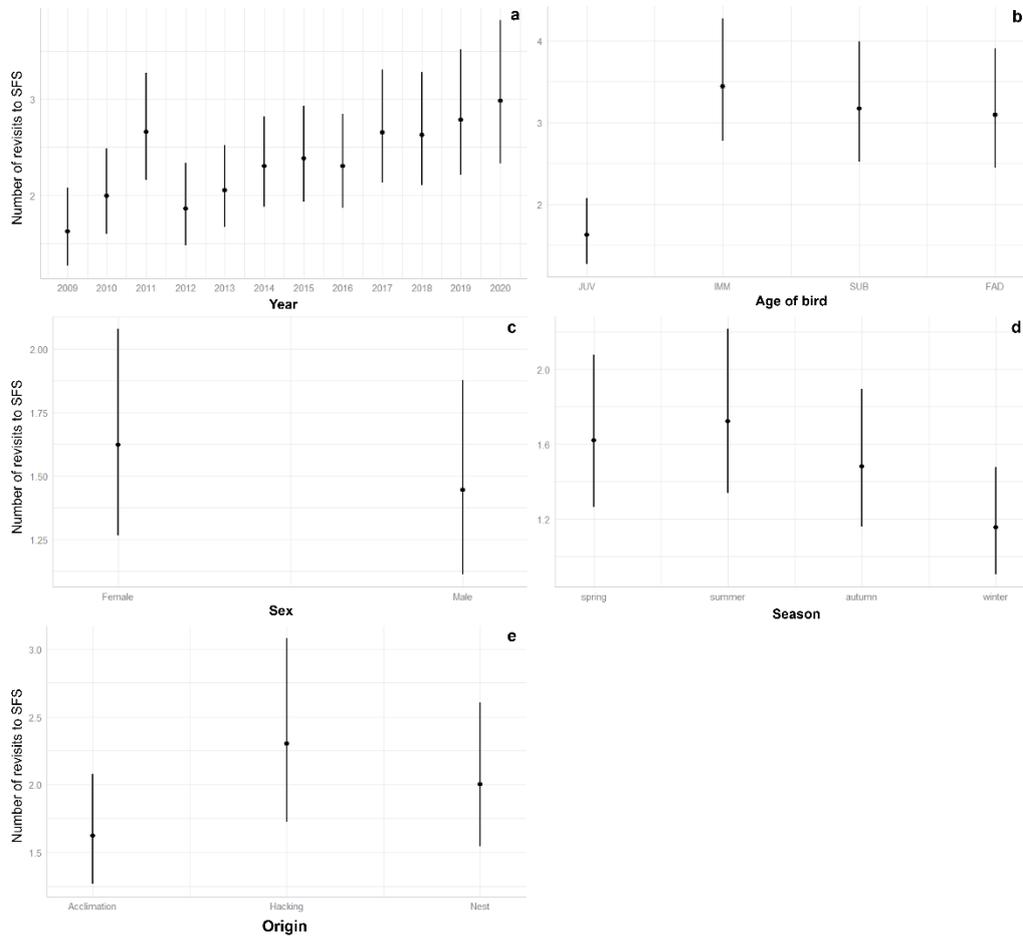

234 Figure 2: Number of Cinereous vultures visiting the 89 supplementary feeding sites (SFS) in Catalonia  
235 and Aragón, each season between 2009 to 2020.

236

237 *Number of supplementary feeding sites visited by age, sex and origin*

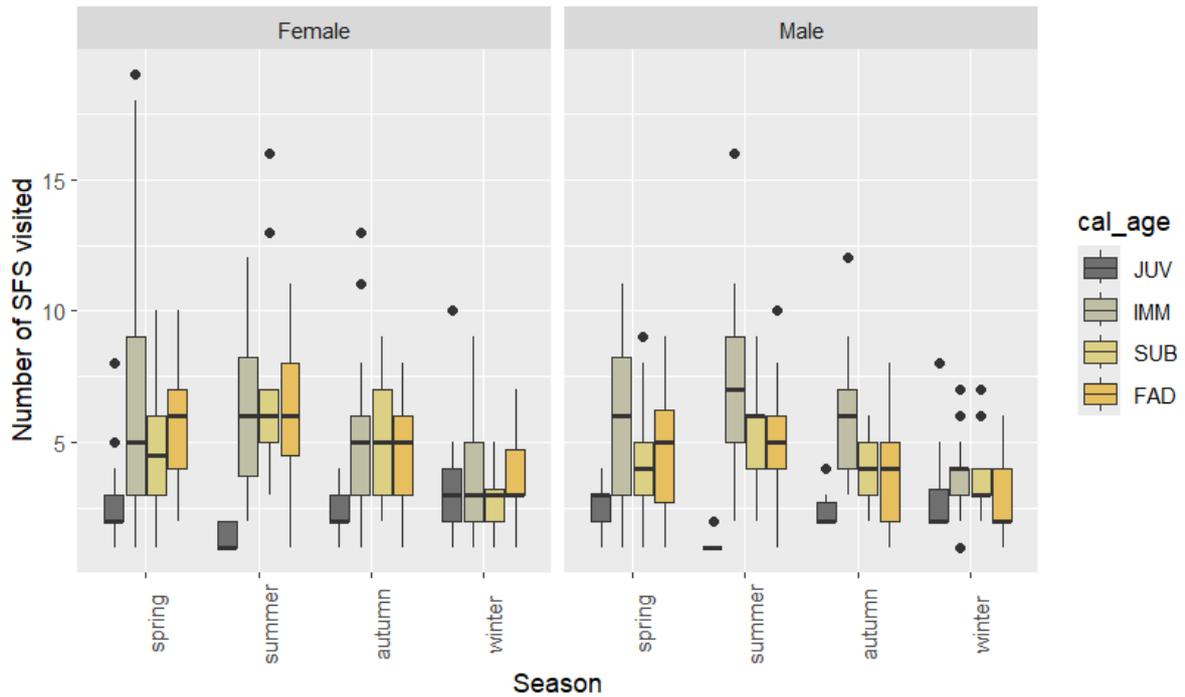

238 Individuals revisited between one and 20 sites within a year (mean: 4.5, SD:  
239 2.65). Accounting for annual variation, there were large inter-seasonal differences in  
240 the number of visits they made to these sites and the time spent in these sites  
241 (Figure 3, Supp Mat). Significantly fewer sites were revisited in winter (*IRR Winter:*  
242 *0.78, CI: 0.68 – 0.89*), compared to all other seasons. Juveniles revisit significantly  
243 fewer sites than all other age groups (*IRR Juvenile: 0.53, CI: 0.45 – 0.61*), although  
244 this difference became smaller in winter. Hacked birds and wild nestlings revisited  
245 significantly more SFS than acclimated birds (*Hacked IRR: 1.42, CI: 1.17 – 1.72*;

246 *Wild IRR: 1.24, CI: 1.08-1.41*; figure 4). Lastly, males visited significantly fewer sites  
 247 that females (*IRR Male: 0.89, CI: 0.81-0.98*).

248

249 Figure 3: Model effects plots including upper and lower 95% confidence intervals, testing the factors  
 250 driving the number of SFS revisited by a. year, b. age group (FAD = Full Adult, IMM = Immature, JUV  
 251 = Juvenile, SUB = Subadult), c. sex, d. season and e. origin.

252

253 Figure 4: The number of different SFS revisited among age groups (acclimated, hacked, wild  
 254 nestlings) across all four seasons, for both females (left) and males (right).

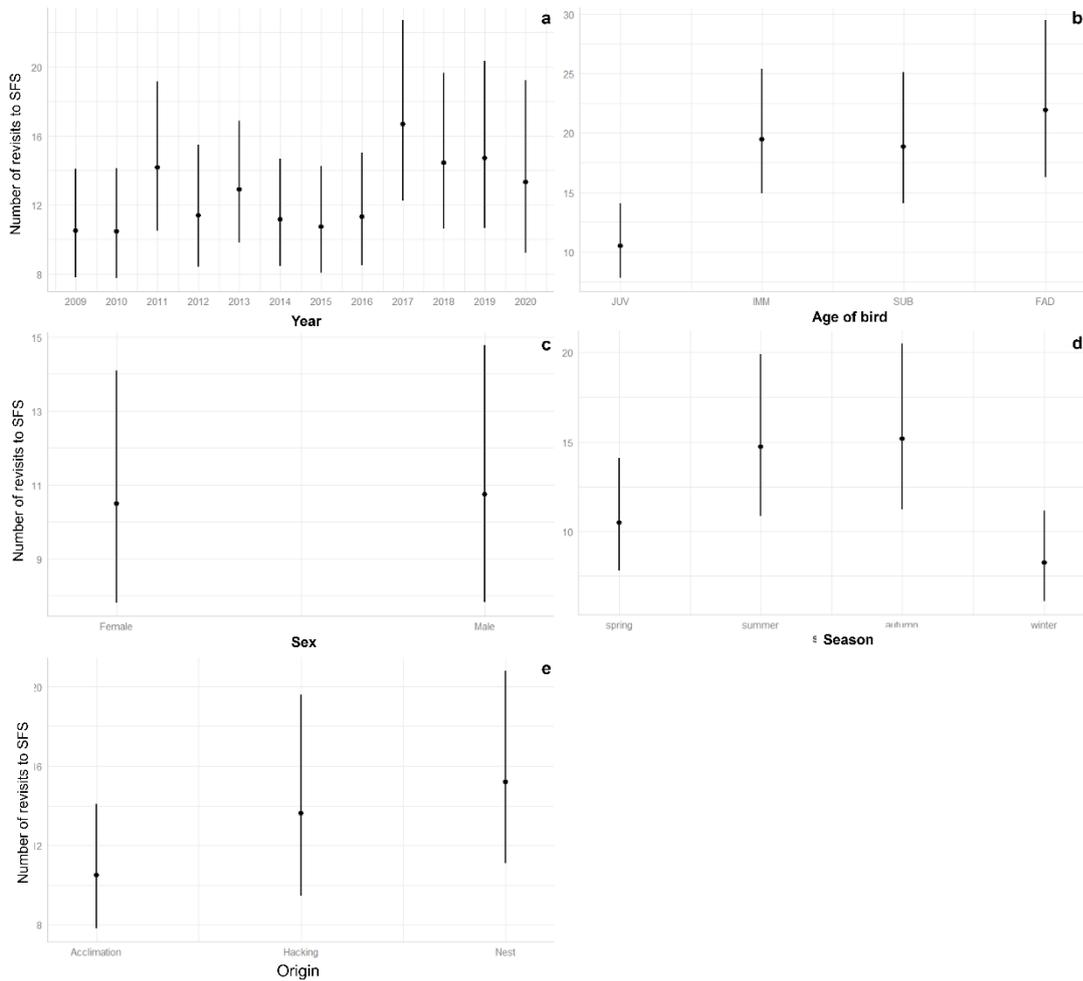

255

256 *Number of revisits made supplementary feeding sites visited by age, sex and origin*

257 Immature, subadult and adult birds made significantly more revisits to SFS than

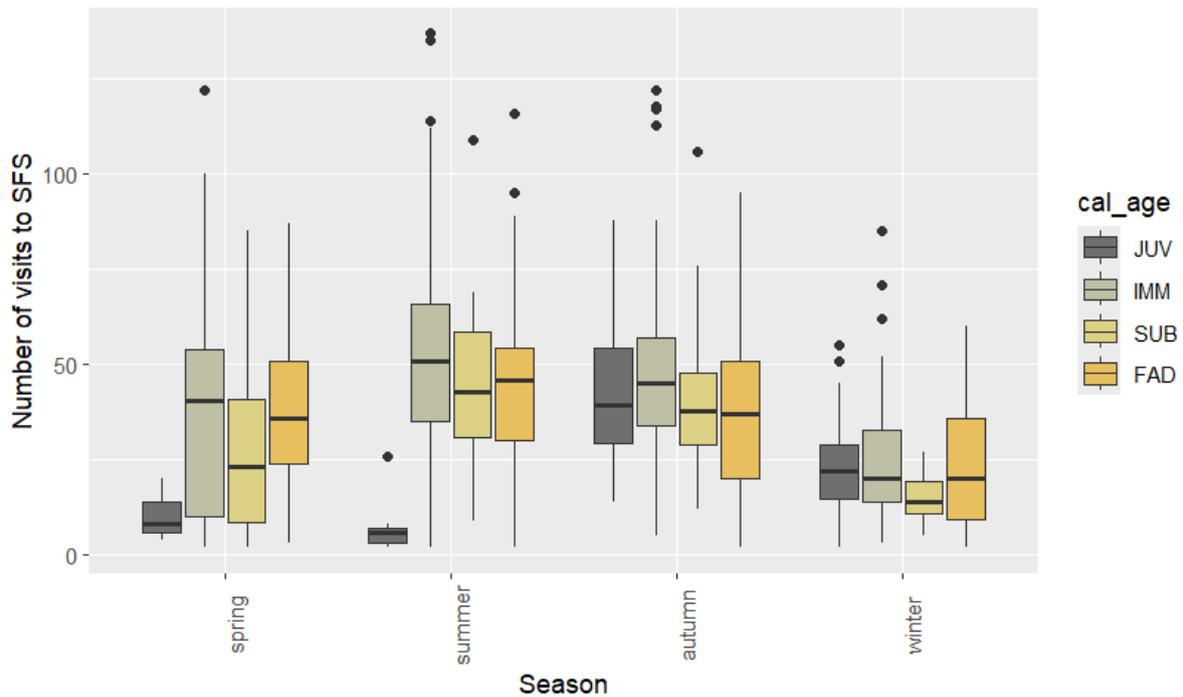

258 juvenile birds (*IRR Juvenile: 0.48, CI: 0.38 – 0.60*), but here only wild born birds

259 made significantly more visits to SFS than acclimated birds (*IRR Wild: 1.45, CI: 1.20-*  
 260 *1.75; IRR hacked: 1.30, CI: 0.97 – 1.73; figures 5 & 6, Supp Mat).*

261

262 Figure 5: Model effects plots including upper and lower 95% confidence intervals, testing the factors  
 263 driving the number of revisits made to SFS by a. year, b. age group (FAD = Full Adult, IMM =  
 264 Immature, JUV = Juvenile, SUB = Subadult), c. sex, d. season and e. origin.

265

266 Figure 6: Number of revisits made to SFS by all four age classes across all four seasons.

267

268 *Time spent at supplementary feeding sites by age, sex and origin*

269 Birds spent an average of 9.7 hours (range: 4.1 - 175 hours) at SFS, but this

270 declined significantly over the years included in the study period (Figure 7 and 8,

271 supp mat). Mean time spent at sites was significantly lower in spring and summer,

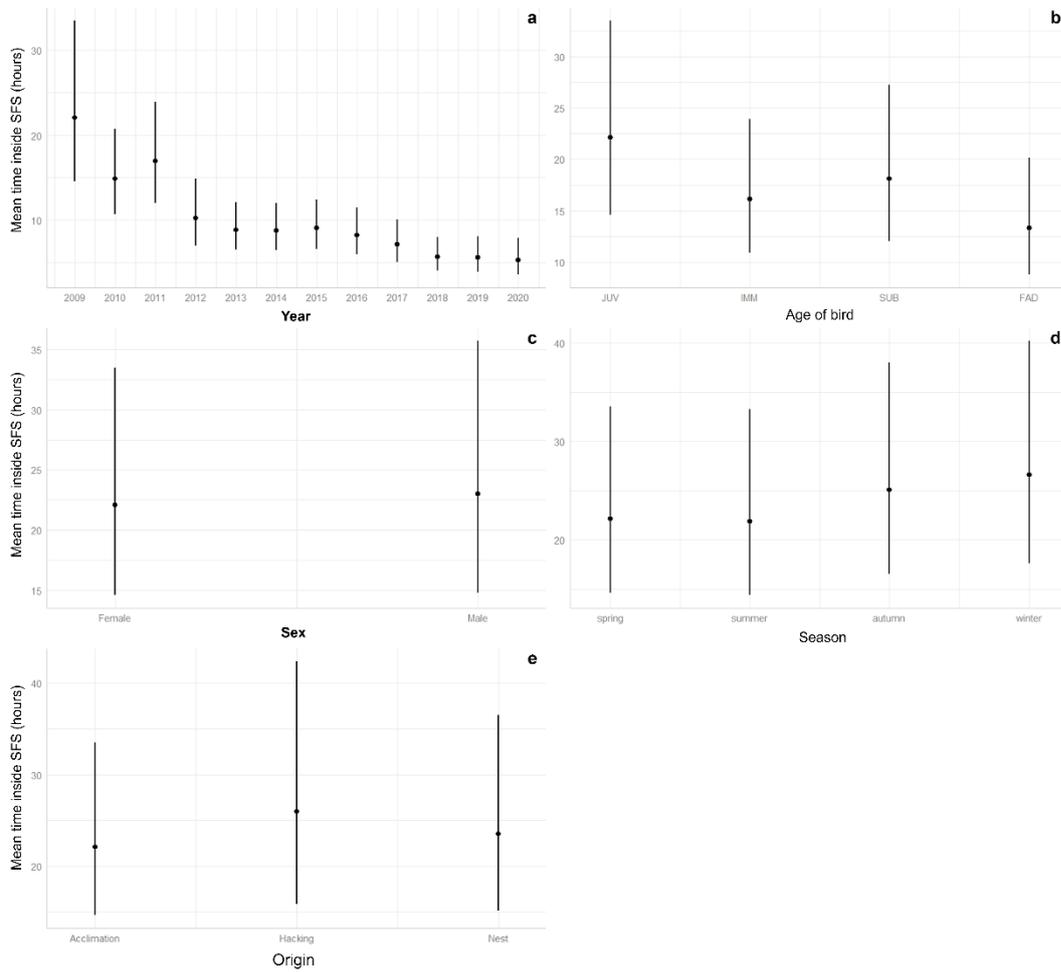

272 (*estimate spring: -0.13, CI: -0.22 – -0.03; estimate summer: -0.14, CI: -0.23 - -0.04;*

273 Figure 8, Supp Mat). However, there was a large amount of heteroscedascity within

274 and across years and seasons, represented by significant dispersion parameters

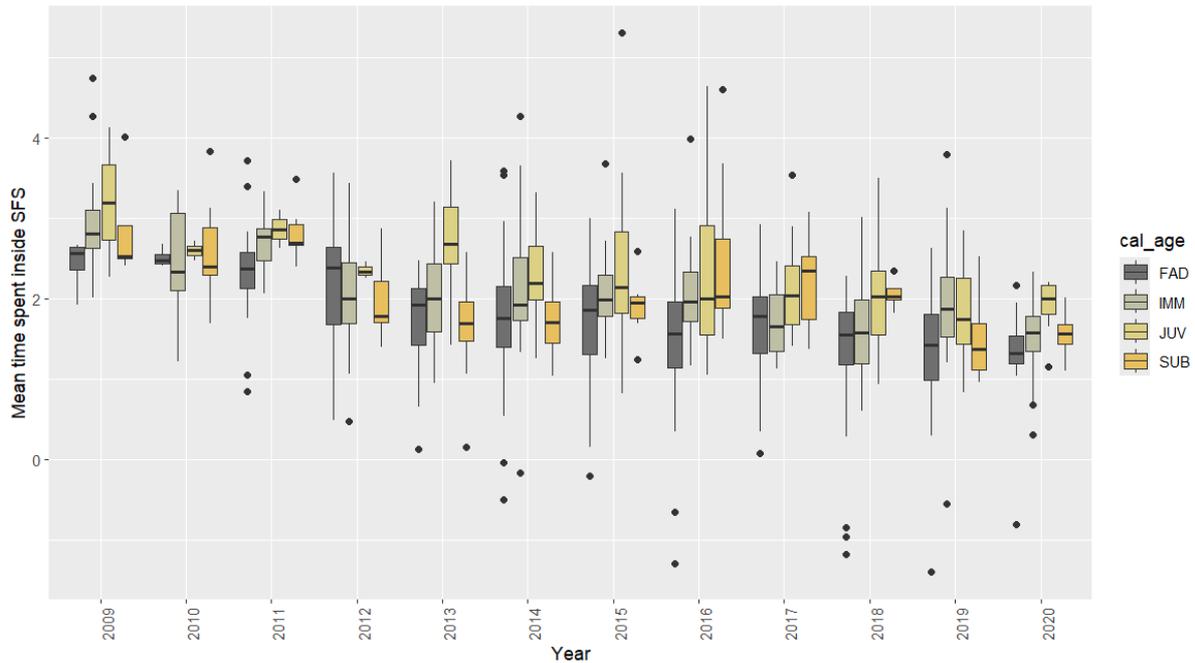

275 (Supp Mat). Adults spent less time compared with the other age groups, particularly

276 juveniles (*estimate juvenile: 0.51, CI: 0.3-0.72, immature: 0.19, CI: 0.02 – 0.36,*  
 277 *subadult: 0.31, CI: 0.16-0.46; Figure 7).*

278

279 Figure 7: Model effects plots including upper and lower 95% confidence intervals, testing the factors  
 280 driving the mean time spent at revisited SFS by a. year, b. age group (FAD = Full Adult, IMM =  
 281 Immature, JUV = Juvenile, SUB = Subadult), c. sex, d. season and e. origin.

282

283 Figure 8: Mean time spent in SFSs (hours; log transformed) among age groups and across years.

284

## 285 Discussion

286 Our analyses revealed significant age-class and release origin differences in  
 287 the number of SFS visited, the number of revisits to these SFS, and the time spent  
 288 there. Supplementary Feeding Sites located in Catalonia and Aragón, were used  
 289 frequently and for long periods of time by Cinereous vultures, both within and  
 290 between years, and among individuals. Temporal differences were also evident, both  
 291 seasonally and interannually, indicating that SFS use is influenced by dynamic  
 292 ecological and life-history factors.

### 293 *Overall population use*

294 Overwhelmingly the most used SFSs were within 10 km of the release site  
 295 and breeding colony, which aligns with the highly philopatric behaviour of Cinereous  
 296 vultures (García-Macía *et al.*, 2023; Tobajas *et al.* 2024). Specifically, the most used

297 SFS were the three closest to the colony, located in the Boumort area. These  
298 received several hundred revisits a year by almost all of the individuals tracked, and  
299 outside of these three SFS the visitation rates declined swiftly.

#### 300 *Differential use among age classes*

301 Our analyses consistently revealed strong age-class differences in SFS use.  
302 Immatures, subadults and adults made more revisits to a larger number of SFS,  
303 whereas juveniles revisited fewer SFS, less often, and spent much longer in these  
304 locations. This pattern aligns with known developmental constraints: juveniles are  
305 inexperienced, have lower flight efficiency (Van Overveld, Gangoso, *et al.*, 2020;  
306 Reznikov *et al.*, 2024), and lack detailed knowledge of the spatial distribution of the  
307 SFS throughout the region and so often explore more widely (García-Macía *et al.*,  
308 2024).

309 Young birds are more social (Van Overveld, Gangoso, *et al.*, 2020), and by  
310 spending more time at specific SFSs, they may facilitate information transfer from  
311 older conspecifics, and gain information as well as competitive foraging skills.  
312 Kleptoparasitism has been recorded in a high percentage of juvenile Spanish  
313 Imperial eagles *Aquila adalberti* (Margalida, Colomer, *et al.*, 2017), as well as  
314 immature Bearded vultures (Margalida and Bertran, 2003), and Black vultures  
315 *Coragyps atratus* (Richard, Contreras Zapata and Angeoletto, 2022); perhaps for  
316 juvenile Cinereous vultures, whose foraging abilities are still underdeveloped,  
317 prolonged use of SFSs may therefore provide both energetic benefits and  
318 opportunities for learning, contributing to their relatively sedentary behaviour at these  
319 sites.

320 Foraging efficiency in vultures is developed over the first few years of life (Efrat *et*  
321 *al.*, 2023), thus by the time they reach potential breeding age (around five years old),  
322 they are likely to have developed a comprehensive map of SFS in the area and to  
323 move directly among known profitable locations. Adult Cinereous vultures, in  
324 contrast, are dominant at feeding sites, able to displace younger individuals (Duriez,  
325 Herman and Sarrazin, 2012; Moreno-Opo *et al.* 2020). Although our results show  
326 they revisit more SFS and do so often, they do not spend more time at such sites,  
327 suggesting perhaps that they are either ‘monitoring’ their environment using well-  
328 developed memory (McGrady *et al.*, 2018), or their dominance at active feeding  
329 stations allows them to feed and leave quicker. Similar patterns have been  
330 documented in adult Egyptian vultures, whose home range sizes are essentially  
331 dictated by the distribution of SFS (López-López, García-Ripollés and Urios, 2014),  
332 and which are smaller than the ranges of immature and subadult birds due to their  
333 ability to exploit these predictable resources efficiently, minimising roaming  
334 (Monsarrat *et al.*, 2013; Morant *et al.*, 2020).

335 The use of SFS by immature and subadult Cinereous vultures (between two and  
336 five years post-fledging) was highly variable, and represent transitional behaviour  
337 between the juvenile and adult life stage. These age classes show different seasonal  
338 patterns, visiting fewer sites in spring, but more sites in summer compared to adults,  
339 who are constrained by nest attendance during the breeding season (Zuberogoitia *et*  
340 *al.*, 2013a; Tobajas *et al.*, 2024). Despite prospecting widely, immatures and  
341 subadults still show their reliance on predictable food resources, including not only  
342 SFS but landfills that may be of lower quality but provide less competitive feeding  
343 (Fernández-Gómez *et al.*, 2022).

344

345

346 *Release origin influence*

347 Release origin also explained variation in the number of SFS revisited and the  
348 number of revisits made to these SFS, although it did not influence the time spent  
349 resident within 1 km of the SFS. Acclimated birds revisited fewer SFS, made fewer  
350 revisits overall, and spent (slightly) less time at these sites compared with hacked  
351 and wild-born birds. This pattern may indicate that acclimated birds are spending  
352 more time exploring the wider region rather than returning to known SFS, whereas  
353 particularly hacked birds rely more on supplemented food and the presence of con-  
354 and heterospecifics (Mihoub *et al.*, 2011), and may represent a lack of exploratory  
355 behaviours in such birds. Success of birds released via aviaries increases generally  
356 with longer periods of acclimation (Fozzi *et al.*, 2023), but is variable, dependent on  
357 the length of time they are acclimated for (Mihoub *et al.*, 2014; Ivanov *et al.*, 2023).  
358 However, lower survival rates of other hacked raptors e.g., hacked juvenile ospreys  
359 *Pandion haliaetus* compared to their wild-born conspecifics, particularly in winter,  
360 likely due to underdeveloped foraging skills, lack of parental care, and reliance on  
361 human-provided during early development (Monti *et al.*, 2014), demonstrating how  
362 captive breeding and translocations can influence social and population structure in  
363 potentially unpredictable ways (Van Overveld, Gangoso, *et al.*, 2020).

364 *Seasonal and annual variation*

365 Season and year also strongly influenced patterns of SFS use, which has also  
366 been found in other vulture research (Monsarrat *et al.*, 2013; Van Overveld *et al.*,  
367 2018; Van Overveld, Gangoso, *et al.*, 2020; Genero *et al.*, 2020; Tréhin *et al.*,  
368 2024b). The strongest differences occurred between winter (December- February)

369 and the remaining seasons; during winter, individuals visited fewer SFSs, did so less  
370 frequently, and spent longer periods at the sites they used. During winter, flying  
371 conditions are generally poor (lower temperatures meaning fewer thermal uplift;  
372 Genero *et al.*, 2020), and hunting activity and subsequent carcass deposition provide  
373 higher food availability, affecting vultures movements and drawing birds to feeding  
374 sites for longer periods (Tobajas *et al.* 2024). This pattern is consistent with  
375 “encamped” foraging behaviour described in other vulture populations, in which  
376 experienced adults remain close to reliable resources under suboptimal flight  
377 conditions (Morant *et al.*, 2020), while juvenile dispersal has not fully begun resulting  
378 in a more intense concentration of multiple age classes (Ivanov *et al.*, 2023; Tréhin  
379 *et al.*, 2024b).

380 We also found a linear increase in both the number of revisits and number of SFS  
381 visited over time (i.e. across years), coupled with a decline in the time spent at these  
382 sites. This does not correspond to more birds being tagged in the later years; more  
383 birds were tagged between 2014-2017, yet the biggest increases in revisits and  
384 locations come after 2017. One plausible explanation is demographic, because from  
385 2017 onwards, a greater proportion of experienced adults were present in the  
386 population, which had developed a comprehensive map of feeding sites, thereby  
387 driving this linear change. Another potential contributing factor may be also related to  
388 a slight delayed response to changes in Spanish sanitary legislation, approved in  
389 2011 but implemented from 2014 (López-Bao and Margalida, 2018), which increased  
390 carcasses availability in the landscape (Fernández-Gómez *et al.*, 2022). Lastly, the  
391 growing presence of acclimated individuals, who have become accustomed to  
392 human-provisioned food during the early stages of reintroduction, may reinforce  
393 population-level reliance on predictable food resources.

394

395 *Population affiliation with SFS and management implications*

396 We observed consistently high use of SFS close to the colony throughout the 12-  
397 years study period. Such spatial concentration raises concerns that the population  
398 may fail to expand into the wider landscape, remaining dependent on a limited  
399 number of predictable feeding sites. Movement, including post-natal dispersal of  
400 vultures, whether released or wild born, are undoubtedly influenced by  
401 supplementary feeding and restocking frequency, and can change over time (see  
402 Fernández-Gómez *et al.*, 2022; Reznikov *et al.*, 2024; Tréhin *et al.*, 2024b). Large  
403 aggregations of vultures may not negatively impact survival, in fact the opposite is  
404 more commonly reported (Margalida, Martínez, *et al.*, 2017; Rousteau *et al.*, 2022),  
405 but they may push juveniles to disperse further, or use less frequently stocked or  
406 poorer quality sites to avoid heavy competition (Fernández-Gómez *et al.*, 2022;  
407 Reznikov *et al.*, 2024). However, movement data of cinereous vultures in the area  
408 show a high residence rate and low long-distance dispersal behaviour of individuals  
409 in all non-adult age classes (Tobajas *et al.* 2024), suggesting that a population  
410 threshold detrimental to young birds has not been reached.

411 Management of SFS must integrate both the ecological and social aspects of  
412 vulture foraging behaviour (Van Overveld, Blanco, *et al.*, 2020), and going forward, a  
413 more dispersed network of lightly stocked feeding sites could better mimic the  
414 natural carcass deposition in the landscape preventing extreme competition and  
415 encouraging more efficient scavenging behaviours (Deygout *et al.*, 2009; Cortés-  
416 Avizanda, Carrete and Donázar, 2010; Dupont *et al.*, 2012; Monsarrat *et al.*, 2013).  
417 Unfortunately, we lacked information on stocking patterns to contribute to the

418 analysis conducted in this study, which could allow us to make a more detailed  
419 examination of the influence of food distribution on movements and behaviour.  
420 Previous research shows that distributing carcasses across a larger number of  
421 feeding sites and a further distances from colonies may encourage dispersal  
422 (Margalida and Colomer, 2012; Reznikov *et al.*, 2024), particularly during spring  
423 when vultures are expanding their ranges. In the context of European health  
424 regulations, the potential closure of SFS for public health reasons may impact vulture  
425 populations. Previous work on SFS closure found a change in diet composition in  
426 Griffon vultures (Donázar, Cortés-Avizanda and Carrete, 2010), and a decrease in  
427 survival, particularly of juveniles (Zuberogoitia *et al.*, 2013b), although it should be  
428 noted that Bearded vultures were not affected by regulations in the same way  
429 (Margalida, Pérez-García and Moreno-Opo, 2017).

430 Closure of large SFS in our study system is likely to change movement patterns,  
431 as seen in the removal of key 'node' sites in Cerecedo-Iglesias *et al.*, (2023).  
432 However, consequences on survival are harder to predict. Depending on the precise  
433 nature of future legislation, if farmers remain able to deposit carcasses on their land  
434 at lower densities, food would still be available in the landscape (Colomer &  
435 Margalida 2025). However, dominant adults that are more skilled at identifying  
436 carcasses in the landscape may push juveniles to disperse further, with potential  
437 survival effects, altering the spatial network use of these younger, non-breeding birds  
438 (Cerecedo-Iglesias *et al.*, 2023). The long-term implications of reduced volume or  
439 quality of predictable resources for future vulture population viability are still unclear;  
440 movements of birds in response to changes in SFS availability should be monitored  
441 and ideally linked to survival, and breeding performance in order to implement any

442 necessary compensatory conservation measures and better plan future release  
443 locations of rehabilitated or captive bred birds.
