3 Abstract

4 (max 350 words)

- 5 1. Functional diversity is widely used and widespread. However, the main package used to compute
6 functional diversity indices `FD` is not flexible and not adapted to the volume of data used in modern
7 ecological analyses.
- 8 2. We here present `fundiversity`, an R package that eases the computation of classical functional di-
9 versity indices. It leverages parallelization and memoization (caching results in memory) to maximize
10 efficiency with data with thousands of columns and rows.
- 11 3. In addition to being more flexible we did a performance comparison with packages that provide analog
12 functions. `fundiversity` was always an order of magnitude quicker than alternative packages.
- 13 4. `fundiversity` aims to be a lightweight efficient tool to compute functional diversity indices, that can
14 be used in a variety of contexts. Because it has been designed following clear principles, it is easy to
15 extend. We hope the wider community will adopt it and we welcome all contributions.

17 ecology

18 Running title (max 45 char.): fundiversity: functional diversity in R

19 Word count (3000-4000 incl. refs & captions): 3511

20 Introduction

21 Functional diversity, the diversity of traits across scales, is a major facet of biodiversity (Pavoine &
22 Bonsall, 2011). It has been widely used across ecological contexts (Cadotte et al., 2011) and has been
23 shown to relate to ecosystem functioning (Díaz & Cabido, 2001; Leps et al., 2006). Many indices exist to
24 characterize it across its three dimensions: richness, evenness, and divergence (Pavoine & Bonsall, 2011).
25 To compute these indices in reproducible ways ecologists rely on computational tools able to crunch the
26 numbers for thousands of species and thousands of sites. In the last few years, R has been the programming
27 language of choice for ecologists (Lai et al., 2019; R Core Team, 2021). The main tool available to compute
28 functional diversity indices has been the `FD` package which has now accumulated more than 1200 citations
29 (Laliberté et al., 2014). But `FD` has been released in 2009 and has since then only received minor updates
30 that stopped in 2015. At the same time, best practices in software development have changed dramatically
31 and new, higher-performance tools have emerged in the R ecosystem. Additionally, since 2009, the size of

ecological datasets has grown exponentially (Farley et al., 2018; Wüest et al., 2020) and high performance computing (HPC) environments have become standard. There is therefore a dire need for a modern package to compute functional indices using state-of-the-art software development techniques and tools.

The main function of the FD package `dbFD()` lets users compute a dozen functional diversity indices in a single call from raw trait data (Laliberté et al., 2014). While great for exploratory analyses this can increase computation time when only a single index is needed. Furthermore, it does not enforce good practice in choosing beforehand the appropriate functional diversity index for the question(s) asked (Legras et al., 2018; Mason et al., 2013; Schleuter et al., 2010). It encourages the user to fish the functional diversity index that matches their predicted relationships (a form of p-hacking). This can lead the users to report all computed functional diversity indices even when there are no clear expectations on different functional diversity facets and/or to report correlated indices (Legras et al., 2018; Mason et al., 2013; McPherson et al., 2018; Schleuter et al., 2010). Computing all indices in a single function also makes long-term maintenance and addition of new indices harder. Finally, it adds an extra performance burden in the case where not all indices are needed.

The average size of datasets analyzed in ecology increased several folds in the last years (Wüest et al., 2020). Considering that most analyses on functional diversity rely on null models that increase the data size by two or three orders of magnitude (Gotelli & Graves, 1996), the need for efficient computation is paramount. First, any improvement of the algorithmic efficiency to compute functional diversity indices could save sensible amounts of time as it is repeated many times. For example, we noted that many R packages that compute functional diversity indices do not leverage matrix algebra with its libraries available that can cut the number of operations by orders of magnitude compared to using a loop directly in R. Second, functional diversity indices are generally computed over many mathematically independent sites. With the rise of multi-core computers, parallelization, i.e. splitting independent computations between different Computing Processor Units (CPUs), is becoming the norm. Very few functional diversity R packages propose parallelization which leaves the burden of implementing it to the user. There have been formidable new developments in this area in R over the last few years with the release `future` framework (Bengtsson, 2020) that allows the user to seamlessly parallelize computations on multiple cores on a single machine or across several machines, or even on a remote cluster without changing execution code. Third, computations on the same input can be cached through a process called memoization (Wickham et al., 2021). This avoids wasting computing power on previously seen inputs. Several functional diversity indices rely on the computation of convex hulls across a multi-dimensional space (Cornwell et al., 2006; Villéger et al., 2008). Caching the results of this costly computation could save time and computing power when measuring the diversity across similar sets, such as sites across a given region.

Increasing discussions are held regarding scientific software robustness and reliability in ecology (Mislan et al., 2016; Poisot, 2015; White, 2015; Wilson et al., 2017). Mainly because most ecologists are self-trained in programming (Farrell & Carey, 2018), these virtuous practices are rarely applied in ecology (Barraquand et al., 2014). For example, unit tests use predefined inputs to compare the software's outputs to expectations (Poisot, 2015). Unit tests have also become standard in R packages since the release of packages streamlining this process, such as `testthat` and `tinytest`. In part because of the relative recentness of the testing frameworks, very few R functional diversity packages provide unit tests to assess that the functions behave expectedly. Automatic tests of one's code are crucial when developing a tool for a wider audience as it may be used across different contexts.

We here propose a modern alternative to FD called `fundiversity` that benefits from modern development practices, necessary features for large-sized datasets (modularity, parallelization, and memoization), and greater flexibility. The package can be easily extended to accommodate additional diversity indices not covered by following a clear design pattern detailed in the next section. We then go through a use case to show how it can be used. We then compare the performance of `fundiversity` against similar packages.

Main features of `fundiversity`

To ensure the consistency of its functions and to make it user-friendly, `fundiversity` follows clear design principles. In this section, we expose its distinctive features and principles.

82 To give maximum flexibility to the users, we tried to build `fundiversity` as modular as possible. Each
83 function in `fundiversity` computes a single functional diversity index, as such if the user is interested
84 in computing a single index, they only need to use a single function. All functions in `fundiversity` are
85 prefixed with `fd_` to avoid conflict with similarly named functions in other packages, as it's becoming
86 standard practice in newer R packages (rOpenSci et al., 2021). In line with its modularity, we focused on
87 making the inputs and outputs of functions coherent. The functions compute functional diversity indices
88 using two main information: a species by traits matrix and a site by species matrix, all functions accept
89 these two objects as first arguments. Because the function outputs one diversity value per site the outputs
90 are always structured similarly: one `site` column that contains the name of its sites and one column named
91 as the computed index (such as `FRic` when computing functional richness). The shape of the output is
92 predictable and easy to be combined with other data.

93 Parallelization can be an easy way to vastly decrease computation speed why leveraging the architecture of
94 modern computers. Almost all functions in `fundiversity` can be parallelized out of the box. `fundiversity`
95 provides parallelization through the `future` backend (Bengtsson, 2020). Parallelization is toggled through
96 a single function call using `future::plan()` before using `fundiversity` functions. Thanks to the flexibility
97 given by the `future` backend, the code to use won't change whether parallelizing across several cores on a
98 single computer, across multiple computers, or on a remote high-performance cluster. The user has only
99 to update the call to `future::plan()` to distribute computations on another infrastructure. Furthermore,
100 the `future` backend provides load balancing so that no cores/units stay idle for too long and the paral-
101 lelized tasks are split evenly. The package contains a dedicated "Parallelization" vignette to guide the
102 users through transforming unparallelized to parallelized code (accessible through `vignette("parallel",`
103 `package = "fundiversity")`).

104 Because functional diversity indices can be computed repeatedly on the same data subset, such as in
105 null models, we can leverage these repeated computations to reuse already computed indices. For example
106 to compute functional richness (`FRic`) the convex hull of the input data has first to be identified, then the
107 program needs to compute the volume of this convex hull. The first step, identifying the convex hull, takes the
108 most time and as such, storing the results of each computed convex hull across a subset of data can vastly cut
109 computation time for a little memory footprint. Memoization consists in doing exactly that, it trades a little
110 of computer memory (keeping the convex hulls stored) for more computation speed. `fundiversity` leverages
111 memoization for all complex computations such as convex hulls. By default, memoization is turned on for
112 `FRic`, the intersection of convex hulls, and `FDiv`. However, it can sometimes create a memory bottleneck
113 which slows down the overall computation. The default behavior can always be overridden through a change
114 in the option `fundiversity.memoise`.

115 Packages depend on one another to avoid reinventing the wheel and thus reuse already developed func-
116 tions. A higher number of dependencies means that a package requires more packages to be installed before
117 its installation. While a high number of dependencies minimizes code replication, it also comes with a
118 high price, because if a single dependency breaks then the whole package cannot be installed anymore (Cox,
119 2019). Inflated dependencies have been identified as a major risk in software and especially scientific software
120 development (Claes et al., 2014; Cox, 2019). `FD` only has four dependencies but other functional diversity
121 packages have many more dependencies. This renders them quite brittle for the users after years of not
122 being actively developed. `fundiversity` has been designed to only have minimal external dependencies, it
123 currently depends on only four external packages: `future.apply` which depends only on two other packages,
124 `Matrix` which is shipped with R, `geometry` and `vegan` on which `FD` also depends.

125 Because user flexibility is key, `fundiversity` has minimal assumptions on the input data structure.
126 All its functions work with data frames, matrices, or sparse matrices alike. Sparse matrices are a different
127 formalization of matrices that do not store explicitly the cells that contain zero. They offer a reduced memory
128 footprint and optimized algebra library for computation (Bates & Maechler, 2021). These matrices are thus
129 specifically relevant for occurrence/abundance matrices that contain many zeros. If the used data have a
130 high proportion of zeros, using sparse matrices can vastly decrease computational time in `fundiversity`.

131 As we underlined in the introduction, automatic software testing, while not 100% foolproof, is needed
132 to increase the confidence in the behavior of functions. It is widespread in computer science but less in
133 scientific software development. This means that software behavior is never assessed against known inputs

134 to make sure it behaves in expected ways. It does not mean that the software is of poor quality, but rather
 135 that some simple errors could introduce unnoticed changes in the behavior of functions. Most packages that
 136 compute functional diversity indices do not include any form of automatic testing. We do want to point out
 137 that most ecologists never received formal training in software development hence the lack of tests (Farrell
 138 & Carey, 2018). We designed `fundiversity` with many unit tests from the beginning, executing at least
 139 every single line of code once (i.e. achieving coverage of 100%).

140 `fundiversity` only computes alpha functional diversity indices, because other recent packages exist
 141 to compute other types of functional diversity indices [Hill numbers, Li (2018); beta-diversity indices,
 142 Baselga_betapart_2012]. We focused on indices available through the `dbFD()` function in the `FD` pack-
 143 age and on indices that could benefit from faster implementation. `fundiversity` contains the following alpha
 144 functional diversity indices: functional richness (FRic), functional dispersion (FDis), functional divergence
 145 (FDiv), functional evenness (FEve), and Rao's quadratic entropy (Q). `fundiversity` also contains a beta-
 146 diversity index as it can be useful to compare functional richness between sites.

Table 1: List of functions available in `fundiversity` to compute functional diversity indices. The two last columns specify which functions are parallelizable and memoizable.

| Function Name | Index Name | Source | Parallelizable | Memoizable |
|----------------------------------|-------------------------------|-----------------------------|----------------|------------|
| <code>fd_fdis()</code> | Functional Dispersion (FDis) | Laliberté & Legendre (2010) | Yes | No |
| <code>fd_fdiv()</code> | Functional Divergence (FDiv) | Villéger et al. (2008) | Yes | Yes |
| <code>fd_feve()</code> | Functional Evenness (FEve) | Villéger et al. (2008) | Yes | No |
| <code>fd_fric()</code> | Functional Richness (FRic) | Villéger et al. (2008) | Yes | Yes |
| <code>fd_fric_intersect()</code> | Functional β -diversity | Villéger et al. (2013) | Yes | Yes |
| <code>fd_raoq()</code> | Rao's Quadratic Entropy (Q) | Rao (1982) | No | No |

147 We made sure the indices were numerically exact by using the test dataset available in Villéger et al.
 148 (2008). The functions in `fundiversity` gave identical results than the one found in Figure 2 of Villéger
 149 et al. (2008). We summarize our comparisons in the numerical correctness vignette accessible through
 150 `vignette("correctness", package = fundiversity)`.

151 Case Study

152 Now that we described the main features of `fundiversity`, we are going to show how to use it in practice
 153 when computing functional diversity indices. As an example dataset, we included in `fundiversity` site-
 154 species and trait data from Nowak et al. (2019). It is accessible through the use of the `data(..., package`
 155 `= "fundiversity")` function. This dataset describes the presence of bird species in South America at
 156 different elevations and four morphological traits.

```
knitr::include_graphics(
  here::here("inst", "manuscript", "figures", "fundiversity_conceptual_diagram.svg")
)
```

157 [Figure 1 about here.]

158 The trait values show species in rows (species are specified as row names) and traits in columns with
 159 trait names as column names. Similarly, the site-species matrix contains sites as rows (site names are row
 160 names) and species as columns (species names are column names).

```
data("traits_birds", package = "fundiversity")
data("site_sp_birds", package = "fundiversity")

head(traits_birds)
```

```

171 ## elev_1000               1                1                1
172 ## elev_1500               1                0                1
173 ## elev_2000               0                0                1
174 ## elev_2500               0                0                1
```

175 Now we obtained trait and occurrence data we need to compute the trait dissimilarity between each pair
 176 of species. As all traits are quantitative we first Z-score them, then we compute the Euclidean distance
 177 between pairs of species.

```
z_traits = scale(traits_birds, center = TRUE, scale = TRUE)

trait_distance = as.matrix(dist(z_traits))
```

178 We can then compute the functional richness of each index at each location. To do so we are using the
 179 `fd_fric()` function. It expects quantitative trait values as the first argument and a site-species matrix as
 180 the second argument.

```
library("fundiversity")

birds_fric = fd_fric(z_traits, site_sp_birds)

head(birds_fric)
```

```
181 ##          site      FRic
182 ## 1 elev_250 66.048816
183 ## 2 elev_500 71.465678
184 ## 3 elev_1000 43.354008
185 ## 4 elev_1500 25.466685
186 ## 5 elev_2000  7.725843
187 ## 6 elev_2500  7.046431
```

188 All other functions in `fundiversity` use a similar structure, the first input is trait data the second one
 189 is a site-species matrix. For Rao’s quadratic entropy computed through `fd_raoq()` functional dissimilarities
 190 can be specified as the third argument:

```
# With functional dissimilarity
birds_raoq = fd_raoq(traits = NULL, site_sp_birds, dist_matrix = trait_distance)

# With trait values
birds_raoq_2 = fd_raoq(z_traits, site_sp_birds)

# Both options give the same results
identical(birds_raoq, birds_raoq_2)
```

191 ## [1] TRUE

192 If all traits are not quantitative it is possible to transform them back into independent traits through
 193 the use of Gower’s distance [Gower (1971); and its extensions: Podani (1999), Pavoine et al. (2009);] then
 194 applying multivariate analysis to obtain orthogonal dimensions (Maire et al., 2015).

195 Performance Comparison

196 To test the actual performance improvements realized by `fundiversity`, we compared computation time
 197 on standardized datasets across similar functions in other packages. We only compared “original” packages
 198 that provide actual functions and not wrappers that depend on other packages to compute functional
 199 diversity indices. We identified 6 packages that computed similar indices to `fundiversity`. Most indices are
 200 computed by the `FD::dbFD()` function but the comparison would be unfair as the function computes many
 201 indices in a single call while functions in `fundiversity` only compute single indices. We considered functions
 202 from: `adiv` (Pavoine, 2020), `BAT` (Cardoso et al., 2015), `betapart` (Baselga & Orme, 2012), `hillR` (Li, 2018),
 203 `mFD` (Magneville et al., 2022), and `FD` (Laliberté et al., 2014) (see Table 2 for the correspondence between
 204 packages). A continuously updated version of this section can be found in the performance comparison
 205 vignette within the `fundiversity` package with `vignette("performance", package = "fundiversity")`.

Table 2: List of functions available in `fundiversity` to compute functional diversity indices and corresponding functions in other packages. The name of the package is indicated before the `::` while the name of the functions (including specified arguments) follows.

| Index Name | <code>fundiversity</code> Functions | Functions in other packages |
|------------------------------|-------------------------------------|--|
| Functional Dispersion (FDis) | <code>fd_fdis()</code> | <code>BAT::dispersion()</code> <code>FD::fdisp()</code> <code>mFD::alpha.fd.multidim(..., ind_vect = "fdis")</code> |
| Functional Divergence (FDiv) | <code>fd_fdiv()</code> | <code>mFD::alpha.fd.multidim(..., ind_vect = "fdiv")</code> |
| Functional Evenness (FEve) | <code>fd_feve()</code> | <code>mFD::alpha.fd.multidim(..., ind_vect = "feve")</code> |
| Functional Richness (FRic) | <code>fd_fric()</code> | <code>BAT::alpha()</code> (tree) <code>BAT::hull.alpha()</code> (hull) <code>mFD::alpha.fd.multidim(..., ind_vect = "fric")</code> |

| Index Name | <code>fundiversity</code> Functions | Functions in other packages |
|-------------------------------|-------------------------------------|---|
| Rao's Quadratic Entropy (Q) | <code>fd_raoq()</code> | <code>adiv::QE()</code> <code>BAT::rao()</code> <code>hillR::hill_func()</code> <code>mFD::alpha.fd.hill(..., q = 2, tau = "max")</code> |
| Functional β -diversity | <code>fd_fric_intersect()</code> | <code>betapart::functional.beta.pair()</code> <code>hillR::hill_func_parti_pairwise()</code> |

For testing purposes, we used datasets of increasing size with the number of species being 200, 500, or 1000; the number of traits 2, 4, or 10; the number of sites 50, 100, or 500. For each set of parameters, we generated a fictional site-species matrix and site-trait matrix, comprised only of continuous trait data. We used these simulated data to perform benchmarks across comparable functions among the selected packages. The benchmark ran 30 times through the `bench` package (Hester & Vaughan, 2021). A summary of the results of the benchmark can be seen in Fig. 2. Full results detailing the timings for each combination of parameters and functions are available in the Supplementary Material (Fig. S4).

[Figure 2 about here.]

We see that for all the indices and functions tested, `fundiversity` is at least an order of magnitude faster than alternative packages. For functional dispersion, `fundiversity` is two orders of magnitude faster compared to `BAT` and `mFD`. For functional divergence, `fundiversity` is one order of magnitude faster than `mFD`. For functional evenness, `fundiversity` is two orders of magnitude faster than `mFD` with sequential and parallelized versions having similar performances. For Rao's quadratic entropy, `fundiversity` is one order of magnitude faster than `hillR` and `mFD`, two orders faster than `adiv`, and three orders of magnitude faster than `BAT`. For functional richness, `fundiversity` is half an order of magnitude faster than the hull version of `BAT`, as well as one and a half order of magnitude faster than its tree version and `mFD`. For functional richness intersection (beta functional diversity), `fundiversity` is two orders of magnitude faster than `betapart` and `hillR`.

[Figure 3 about here.]

As shown on Fig. 2, on average the parallelized versions of `fundiversity` functions executed an order of magnitude faster than the sequential versions. For functional richness we even observed a difference of two orders of magnitude. However, for functional dispersion, parallelization increased overall computation time. This may be due to inherent parallelization issues: there is an overhead cost when splitting tasks across multiple cores of a computer. The efficiency of parallelization depends on the difficulty of the tasks that are split between cores. In the case of functional richness, the main task is computing the convex hull, which is computationally costly, that is why parallelization increase performance in this case. While computing functional dispersion is simpler, and as such, does not benefit from being split across different cores. Different values for the number of cores, species, traits or sites produce qualitatively the same results (full results in Fig. S5).

One important note regarding parallelization in `fundiversity`, is that it is important to avoid doing both memoization and parallelization simultaneously. Memoization creates a cache to avoid recomputing results, and the cache may be corrupted if several cores access the same results at the same time. We noticed that toggling memoization while performing parallelization severely increase total computational time, compared to sequential performance.

Note that these benchmarks only assess the packages computation speed and in no way any package intrinsic quality or usefulness. We're comparing `fundiversity`, a package whose one of the main goals is performance, with other packages that may have other primary goals and offer other benefits. Most other packages offer more features than simply computing functional diversity indices. For example, several packages offer nice default visualization functions to plot the different diversity indices, while we explicitly

245 considered that visualization functions were not part of `fundiversity` and let the users decide how they
246 want to plot their indices.

247 Conclusion

248 We proposed a modern alternative R package to compute functional diversity indices. This package fol-
249 lows current best development practices and leverages modern features like parallelization and memoization
250 to increase its performance. This is only made possible by recent developments which were for the most part
251 not available at the time when alternative packages came out. `fundiversity` does not propose to replace
252 the entire toolkit for the researcher interested in functional diversity (including the upstream selection of
253 the traits and building of a functional space) but instead focuses on improving the most computationally
254 costing step: computing functional diversity indices. We hope it will be a useful contribution to this toolkit.
255 This package aims to always be a work in progress and we welcome contributions from interested users and
256 developers.

265 Data Availability

266 `fundiversity` is available on CRAN through `install.packages("fundiversity")` as well as on GitHub
267 at <https://github.com/Bisaloo/fundiversity>, for archival all releases are available on Zenodo at <https://doi.org/10.5281/zenodo.4761754>. The data used in this article are available from the package, through
268 `data(package = "fundiversity")` call.

378 **List of Figures**

379 1 Conceptual diagram showing the input and typical output data from ‘fundiversity‘ functions.
380 Input data are generally a site-species table and a species-traits table, and the output gives
381 back a table of functional diversity index per site. 12
382 2 Timing comparison across functional diversity indices between packages. Each point repre-
383 sents the execution time of one run using a simulated dataset, the points are transparent and
384 jittered to avoid overplotting. We here show the performance results considering only a single
385 set of parameters with 4 traits, 500 species, and 100 sites, repeated 30 times. 13
386 3 Timing comparison between parallel and sequential version of fundiversity functions across
387 functional diversity indices. Each point represents the execution time of one run using simu-
388 lated datasets with fixed properties (4 traits, 100 sites, 500 species), the points are transparent
389 and jittered to avoid overplotting. The parallel version ran across 6 cores. 14
390 4 Performance comparison across functions of different packages over a range of parameters
391 (number of traits, species, and sites). Note that each combination of parameters ran 30
392 iterations. The lines show trends of execution time in function of number of sites of the input
393 dataset. 15
394 5 Performance comparison across internal functions over a range of parameters (number of traits,
395 species, and sites) and different parallelization parameters. Note that each combination of
396 parameters ran 20 iterations. The lines show trends of execution time in function of number
397 of sites of the input dataset. 16

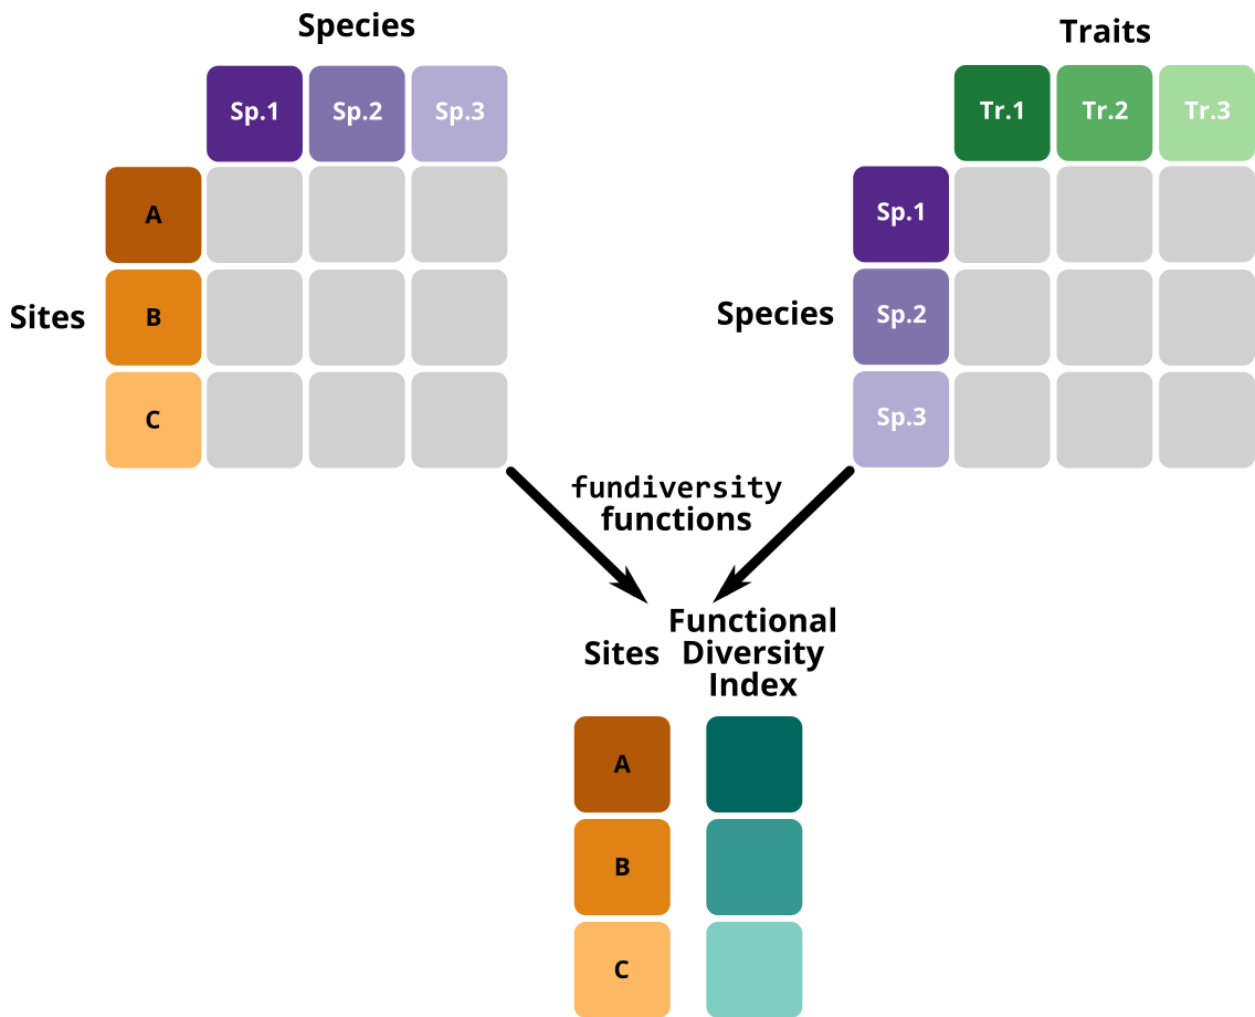

Figure 1: Conceptual diagram showing the input and typical output data from 'fundiversity' functions. Input data are generally a site-species table and a species-traits table, and the output gives back a table of functional diversity index per site.

Figure 2: Timing comparison across functional diversity indices between packages. Each point represents the execution time of one run using a simulated dataset, the points are transparent and jittered to avoid overplotting. We here show the performance results considering only a single set of parameters with 4 traits, 500 species, and 100 sites, repeated 30 times.

Figure 3: Timing comparison between parallel and sequential version of fundiversity functions across functional diversity indices. Each point represents the execution time of one run using simulated datasets with fixed properties (4 traits, 100 sites, 500 species), the points are transparent and jittered to avoid overplotting. The parallel version ran across 6 cores.

Figure 4: Performance comparison across functions of different packages over a range of parameters (number of traits, species, and sites). Note that each combination of parameters ran 30 iterations. The lines show trends of execution time in function of number of sites of the input dataset.

Figure 5: Performance comparison across internal functions over a range of parameters (number of traits, species, and sites) and different parallelization parameters. Note that each combination of parameters ran 20 iterations. The lines show trends of execution time in function of number of sites of the input dataset.
