## 38 **Funding**

39 This project was supported by the Australian Government's National  
40 Environmental Science Programme through the Threatened Species  
41 Recovery Hub. C. Y. was supported by University of Queensland as a  
42 Research Assistant funded by Green Fire Science research group and as a  
43 PhD candidate at University of Western Australia funded through the  
44 Australian Research Council Discovery Projects (DP200102877) and the  
45 Australian Government Research Training Program Scholarship.

46

## Abstract

1. Budgeting for biodiversity conservation requires realistic estimates of the costs of threat abatement. However, data on the costs of managing threats to biodiversity is often unavailable or unable to be extrapolated across relevant locations and scales due to a lack of transparency and consistency in how it was collated. Conservation expenditure largely occurs without a priori estimates costs across broad scales and is not recorded in ways that can inform future budgets nor the comparison of action cost-effectiveness.
2. We provide transparent, broadly applicable cost models for 18 Threat Abatement Strategies aimed at managing the processes threatening biodiversity across the Australian continent. We define the actions required to implement each strategy and use a consistent structure to classify costs into components of labour, travel, consumables and equipment. We drew upon expert knowledge and literature to parameterise and apply each model, estimating the implementation cost of each strategy across Australia, accounting for spatial variables such as threats, terrain, and travel distance.
3. The baseline cost estimates generated by the models for threat abatement strategies varied considerably between strategies and across Australia, ranging from \$24 - \$0.88m per km<sup>2</sup>/year (\$0.24 - \$8.8k per ha/year). Across all strategies, Labour made up most of the action costs (49%), followed by Consumables (37%), Travel (13%) and Equipment (2%). A Monte Carlo simulation indicated that threat abatement strategy costs had on average an upper and lower bound of +44% and -33% of the baseline cost.
4. **Policy Implications** - We provide a consistent and transparent approach to budgeting for threat abatement strategies, aiming to improve conservation planning processes, outcomes and reporting requirements across Australia. Understanding the budget required to achieve threat management outcomes can aid revenue-raising and target setting. The models, cost layers and estimates we generate

79 provide the basis for a nationally consistent approach for estimating  
80 and recording the cost of biodiversity management strategies, which  
81 should be continually improved and updated over time.

## 86 **Introduction**

87 Understanding the financial resources required to manage threats and  
88 achieve conservation goals is important for budgeting, investigating value of  
89 alternative actions, target-setting and prioritising limited conservation  
90 resources (Cook *et al.* 2017; Iacona *et al.* 2018). However, the costs of  
91 implementing a conservation action are often challenging to estimate, and  
92 most conservation investments occur without reliable estimates of their return  
93 on investment (Auerbach, Tulloch & Possingham 2014). This is, in part, due  
94 to the lack of readily applicable cost data available to the conservation sector  
95 (Iacona *et al.* 2018). Where conservation cost data are available it often lacks  
96 critical information on how estimates are produced, and what is included and  
97 excluded (Armsworth 2014). The influence of a cost layer in prioritisation can  
98 be as high as the joint influence of thousands of species layers (Kujala *et al.*  
99 2018), and absence of high quality cost data can be sub-optimal (Naidoo *et*  
100 *al.* 2007; Carwardine *et al.* 2008) driving up to 35% loss of environmental  
101 value benefits (Pannell & Gibson 2016).

102

103 Local and regional scale conservation budgeting tools (Iacona *et al.* 2018;  
104 Wenger *et al.* 2018; Thomson *et al.* 2020) can contribute to more accurate  
105 project cost predictions (Cook *et al.* 2017), improve cost data collection  
106 processes (Iacona *et al.* 2018) and estimate the efficiency of delivering  
107 conservation outcomes at the scale that the models have been applied  
108 (Margoluis *et al.* 2009). However, estimates generated by these tools are not  
109 generalisable for larger scale strategic planning that must occur across vast  
110 areas and land tenures. Hence, cost estimates cannot easily be compared  
111 across studies and applications, nor confidently extrapolated to other  
112 locations (Cook *et al.* 2017; Iacona *et al.* 2018). For example, while it is  
113 possible to find one or more locations with accurate cost information for  
114 managing weeds, we lack information on larger scale to strategically budget  
115 at a regional or continental scale (Kearney *et al.* 2019). The knowledge gap  
116 in the budget required to achieve a conservation outcome at the broad-scale  
117 cannot easily be filled by combining multiple sources of local scale cost

118 estimates that have been derived using different approaches or delivery  
119 agents. Further effort is needed to build cost models and budgets applicable  
120 across broad landscapes, with adjustable assumptions to enable transparent  
121 comparisons of costs across different regions, actions and contexts.

122

123 Here we address this knowledge gap by developing and implementing a  
124 systematic approach to model the costs of conservation threat abatement  
125 strategies across Australia. Australia is a mega-biodiverse nation whose  
126 biodiversity faces significant threatening processes over vast landscapes,  
127 tenures and ecosystem types (Jackson 2016; Kearney *et al.* 2019). Building  
128 on previous efforts (Wenger *et al.* 2018; Thomson *et al.* 2020), we developed  
129 models that include a comprehensive range of actions, with underlying  
130 assumptions assigned to the cost components of labour, travel, consumables  
131 and equipment. We model generic and scalable actions, rather than  
132 attempting to piece together cost information collected using different  
133 approaches and locations. In doing so, we provide estimates of the costs of  
134 abating 18 major threats to Australia's biodiversity, and a set of transferable,  
135 transparent cost models and spatial cost layers that can be used for planning  
136 and prioritisation efforts at national and other broad scales. These estimates  
137 are reflective of average efforts across broad landscape and assumptions  
138 should be modified for finer resolution analyses where improved local scale  
139 information exists.

## 140 **Methodology**

141 Our approach applies the best available national scale knowledge on threat  
142 abatement for the benefit of biodiversity and builds upon existing approaches  
143 for estimating the costs of threat abatement actions. We collated information  
144 and methods on threat abatement actions and costs from the scientific and  
145 grey literature, including Australian threat abatement plans (TAP), Australian  
146 threat abatement advices and action plans, and available data and  
147 approaches from two existing programs: the Saving our Species program in  
148 NSW (DPIE 2021) and DELWP's Strategic Management Prospects in

149 Victoria (Thomson *et al.* 2020). We established a working group of 47  
150 experts, with whom we developed strategies, actions and cost estimates at  
151 two online workshops and discussions. Six of the experts are co-authors in  
152 this paper and the complete list is provided in the acknowledgements.

153

154 We applied this knowledge and information to estimate the costs of threat  
155 abatement strategies following three steps (Fig. 1). First, we described each  
156 threat abatement strategy (hereafter, TAS), the actions involved to complete  
157 each strategy over a 30-year time frame. Within each action (e.g. pre-action  
158 office planning, aerial baiting, post-action valuation), we defined four cost  
159 components: labour (L), travel within site (T), consumables (C) and  
160 equipment (E) (Table 1) (see Supp. Material 4 for details). Second, we  
161 structured generic models to estimate the cost of each strategy, as a function  
162 of the contributing action costs (spatial and non-spatial) and travel to site  
163 costs for all actions included in the strategy. Third, we extrapolated the  
164 estimated action and travel costs across Australia to create spatial cost  
165 layers at 1km<sup>2</sup> resolution, using information on the locations of threats,  
166 landscape resistance levels and travel time. We created spatial cost models  
167 for each TAS separately for areas across Australia where the strategy is  
168 likely to be relevant, based on available information about the spatial extent  
169 of threats.

- Define actions, TAS and assumptions for cost components, through literature and expert consultation  
**Output 1: TAS assumptions**

**Example of Invasive Predator TAS**

- Annual aerial baiting:
- 1 FTE annually to administer bait from aircraft (Labour)
  - 50 baits/km<sup>2</sup> at \$0.50/bait delivered at 500m transects (Consumables)
  - Sweating rack of \$15k to prepare baits (Equipment)
  - Aircraft at \$850/hr for petrol and pilot flying at 130km/h with refueling distance of 400km and transit speed of 250km/h (Travel).
  - Accommodation and food at \$210 per person per day (Consumables).
  - Aircraft at \$880/hr (\$850+\$30 hourly travel compensation labour rate) for aircraft, pilot and person from the closest airport (Travel).

- Estimate cost/unit and trips required  
 - Discount, annualise and apply multipliers  
**Output 2: Cost/km<sup>2</sup> per action and trips required per action**

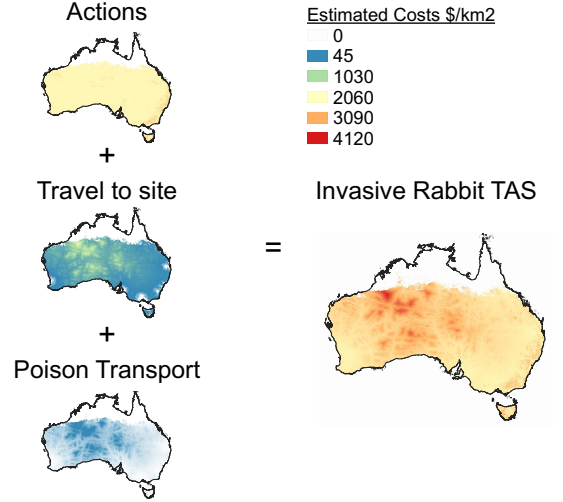

**Example of invasive weed management TAS in a typical location**

Action	Annualised NPV/km <sup>2</sup>	Trips to site
<b>Invasive weed management</b>		
Arid/semi-arid - Moderate	\$ 24,300	77
<b>Standardised Actions</b>		
Pre-action office planning	\$ 66	0
Pre-action field planning	\$ 44	1
Post-action monitoring	\$ 44	1
Post-action evaluation	\$ 66	0
<b>Grand Total</b>	<b>\$ 24,519</b>	<b>79</b>

- Create national cost layers based on cost/km<sup>2</sup>, threats and resistance + travel cost layers based on trips required and travel\_distance  
**Output 3: Cost and travel layers by TAS**

**Example of invasive rabbit TAS**

170  
 171  
 172  
 173

Figure 1. The three-step methodology overview to estimate costs for Threat Abatement Strategies (TASs). The broad steps are shown at the top row, the middle row summarises the generic methodology that applies to each TAS, and in the bottom row we demonstrate the output of each step with an example.

## 174 **Defining Threat Abatement Strategies and actions**

175 We defined 18 strategies to abate the key threats to Australia’s terrestrial and  
176 freshwater biodiversity, using the current literature on the threats to  
177 Australia’s biodiversity and existing and future potential threat management  
178 strategies. We worked with experts in biodiversity conservation and  
179 management (see Acknowledgements) to define a Threat Abatement  
180 Strategy (TAS) to abate each threat presented by Ward *et al.* (2021), who  
181 define threats impacting Australia’s EPBC listed threatened species (1,796  
182 species). We assumed the threats impacting threatened species would be  
183 relevant to the range of Australia’s biodiversity. Where possible we grouped  
184 threats of similar nature that could be abated under the same TAS (see  
185 Supp. Material 1 for the assignment of TAS to the threats compiled by Ward  
186 *et al.* (2021)).

187  
188 For each strategy (detailed in Supp. Material 2) we defined the set of actions  
189 involved throughout the planning, implementation, and evaluation process of  
190 carrying out the strategy (adapted from (Iacona *et al.* 2018; Wenger *et al.*  
191 2018; Carwardine *et al.* 2019). The implementation actions were specific to  
192 each strategy, however we defined four standardised actions that covered  
193 the planning and evaluation stages for all threat abatement strategies: pre-  
194 action office planning, pre-action field planning, post-action monitoring and  
195 post-action evaluation, and made general assumptions on the level of effort  
196 required for each (Table 1).

197  
198 We defined implementation actions generically, rather than attempting to  
199 prescribe site-specific details of actions, which would require more detailed  
200 local scale information. However, actions and their costs vary based on  
201 spatial variables like terrain ruggedness, vegetation type and human  
202 population density (see Supp. Material 3). All actions and strategies were  
203 considered over a 30-year time period, and we assigned a frequency of re-  
204 occurrence for each action (e.g. every “X” years over 30 years). We assumed

205 all actions are performed humanely, are undertaken by competent/skilled  
 206 practitioners that follow best practices, and that landholders and stakeholders  
 207 are willing to participate.

208

209 Table 1. Standardised planning and evaluation actions that are included in  
 210 each Threat Abatement Strategy, the general description of each, and the  
 211 assumed effort required for each action and finally, the cost components  
 212 relevant to each action. These standardised actions are additional to the on-  
 213 ground implementation efforts involved with each strategy. The assumptions  
 214 regarding amount of effort used was based on expert knowledge and grey  
 215 and published literature (see Supp. Material 2).

<b>Action</b>	<b>Description</b>	<b>Effort</b>	<b>Cost components</b>
Pre-action office planning	Office-based planning to coordinate action logistics	3 weeks of off-site labour per standardised management area (see Section 2.2)	Labour only
Pre-action field planning	Evaluation of site context, threat status and habitat condition.	On-site survey of 30% of the management area	Labour, travel, consumables and equipment.
Post-action monitoring	Monitor the threat abatement impact within management area	On-site survey of 30% of the management area	Labour, travel, consumables and equipment.
Post-action evaluation	Reporting requirements, data analysis and integrating insights into management	3 weeks of off-site labour per standardised management area	Labour only

216

217

## 218 **Model the costs of actions and strategies**

219 We designed a generic cost model structure that can be applied to each  
220 threat abatement strategy and used it to estimate the costs of each strategy.  
221 The process of applying the cost models included estimating the action costs  
222 and travel to site costs associated with each strategy and conducting an  
223 uncertainty analysis on the cost inputs to test their robustness.

### 224 **Generic Cost Model**

225 The total cost of a strategy within a management area is a function of its  
226 spatial action costs, travel to site costs, and non-spatial costs (Equation 1),  
227 with the action costs per km<sup>2</sup> calculated as the sum of the cost components  
228 (Equation 2), and the travel to site cost per km<sup>2</sup> determined by the cost of the  
229 return trips required for each action (Equation 3). To account for efficiencies  
230 of scale we typically assumed actions were carried out over a management  
231 area window of 100 km<sup>2</sup> (Table 2). The time horizon for each action, and  
232 hence the cost models, is 30 years from 31<sup>st</sup> of December 2020 to 31<sup>st</sup> of  
233 December 2050. We present all final cost estimates as an annualized cost of  
234 the 30-year Present Value (PV) as at 31<sup>st</sup> of December 2020 accounting for  
235 the frequency of actions and using a real discount rate of 4% and assuming  
236 constant real costs into the future (see Supp. Material 3 for detail). The  
237 description of model parameters is shown in Table 2.

238

$$\begin{aligned} 239 \quad TAS \text{ cost} &= \sum_{actions} (Action \text{ cost per km}^2 \times Action \text{ area}) \\ 240 &\quad + \sum_{actions} (Travel \text{ to site cost per km}^2 \text{ per km distance} \\ 241 &\quad \times Action \text{ area} \times Distance \text{ to site} \times 2) \\ 242 &\quad + \sum_{actions} Non \text{ spatial costs} \end{aligned} \tag{1}$$

244 where

245 *Action cost per km<sup>2</sup>*

246 
$$= \sum_{L,T,C,E} \text{Annualised Cost components} \times \text{multipliers}$$

247 
$$\times (\text{management grid window size})^{-1}$$

248 (2)

249 and

250 *Travel to site cost per km<sup>2</sup> per km distance*

251 
$$= \text{Annualised Travel cost per hour} \times (\text{transit speed})^{-1}$$

252 
$$\times \text{Number of trips required} \times \text{multipliers}$$

253 
$$\times (\text{management grid window size})^{-1}$$

254 (3)

255

256 Table 2. Cost model parameter description from Eq. 1, 2 and 3.

Cost Model		
Equation	Parameter	Description
1	Action Cost unit	Per km <sup>2</sup> unless specified otherwise, e.g. per km of river length or per in-stream structure.
1	Action area	Spatial extent of action, based on relevant threat layers
1	Distance to site	Distance to closest city/airport to each grid-cell, multiplied by 2 for return trip
1	Non-spatial costs (if any)	High level efforts that do not vary spatially, e.g. policy and education
2	Annualised Cost components	A Present Value (PV) was calculated for the costs accounting for different payment frequencies, then the PV was annualised over 30 years. The components included Labour (L), travel within site (T), consumables (C) and equipment (E)
2,3	Multipliers	30% for on-costs that are only applied to labour and 10% for on-site contingencies that only apply

		to costs that are incurred on-site. These can be adjusted by the end-user.
1,2,3	Management grid window size	Standard management area of 100km <sup>2</sup> unless specified otherwise e.g. per 100km waterway or per instream structure
3	Number of trips	Visits required for onsite action to be completed in multiples of 21-day periods of field work
3	Annualised Travel cost	Cost per hour includes vehicle cost and time compensation cost for personnel. A PV was calculated for the costs accounting for different payment frequencies, then the PV was annualised over 30 years.

---

257

258 For each action we calculated the aggregate present value of costs over 30  
 259 years and converted the result to an equivalent annual value (an annuity).  
 260 Using the standard annuity due formula (Chan & Tse 2017) (Equation 4),  
 261 cash flows were first calculated as a PV across the time horizon adapted for  
 262 the differing payment frequencies (Equation 5), then the PV values were  
 263 annualised using the standard annuity due formula (Equation 4). This allowed  
 264 cash flows to be consistent and additive across all actions and strategies.

265

$$266 \quad \ddot{a}_n = P \times \frac{1 - (1 + i)^{-n}}{i} \times (1 + i) \quad (4)$$

268 Where  $\ddot{a}_n$  is the annuity due at time zero for  $n$  payments,  $P$  is the regular  
 269 cash flow incurred from period 0 to period  $n - 1$ , and  $i$  is the real discount  
 270 rate.

$$271 \quad \ddot{a}_{rk} = P \times \frac{1 - (1 + I)^{-rk}}{I} \times (1 + I) \quad (5)$$

272

273 Where  $\ddot{a}_{rk}$  is the annuity due at time zero for  $r$  repayments that occur at the  
274 start of every  $k$  periods such that  $n = rk$ , and the adapted real discount rate  $I$   
275 across the  $k$  periods such that  $(1 + I) = (1 + i)^k$

276

277 We included two cost multipliers, which were combined multiplicatively to  
278 each relevant cost component. For labour on-costs, we applied a 30%  
279 multiplier to Labour costs based on the on-cost percentages used for  
280 professional staff at the University of New South Wales in NSW and ACT  
281 (HR 2018b; HR 2018a) and on-costs applied to action costs in South Africa  
282 (van Wilgen *et al.* 2016). On-costs account for employee support, office  
283 space and IT equipment, insurance, superannuation and leave, etc. For on-  
284 site contingencies, a 10% multiplier was applied to Labour, Travel and  
285 Consumable cost components for on-site based work, to account for  
286 unforeseen circumstances like bad weather and logistical and operational  
287 challenges. The 10% was chosen based on the collective advice of the  
288 expert group.

## 289 Action and travel to site costs

290 Based on the model assumptions (see Supp. Material 3) and cost component  
291 assumptions (see Supp. Material 4), we modelled the action costs within  
292 each TAS at the relevant unit of measurement (Eq. 2) (see Supp. Material 5).  
293 The relevant unit of measurement was typically per km<sup>2</sup>, with management  
294 actions that occurred along a waterway estimated per km of waterway length  
295 (e.g. waterway fencing in Grazing Management TAS, Trout Barrier  
296 Installation in Invasive fish management TAS), and management actions that  
297 occurred for Hydrology TAS were estimated per in-stream structure (see  
298 Supp. Material 2 & 5). We converted the PV costs for each action to an  
299 equivalent annual value (see annuity calculation above). We then divided all  
300 the costs by the standardised area to calculate a per unit of measurement  
301 and applied the corresponding cost multipliers for the relevant cost  
302 components. We estimated the Travel to site costs per km<sup>2</sup> per unit area (Eq.  
303 3) driven by the mode of transport, travel distance and the number of trips

304 required (for detail see Supp. Material 3 for cost models see Supp. Material  
305 5).

## 306 **Uncertainty in Costs**

307 We conducted a Monte Carlo analysis to represent the uncertainty around  
308 the cost inputs. We created probability distributions for global variables that  
309 were common across the TASs and these were often labour related, and  
310 uncertainty of action-specific variables were not included i.e. bait costs, bullet  
311 costs etc. We assume that the cost estimates generated from our cost inputs  
312 represent our baseline estimates that correspond to the median value (50<sup>th</sup>  
313 percentile), we then subjectively set values for the lower bound and upper  
314 bound values that correspond to the 10<sup>th</sup> and 90<sup>th</sup> percentile. We created  
315 individual probability distributions for 18 parameter values that were common  
316 across the TASs, with a 25% probability for the lower bound, 50% for the  
317 baseline values and 25% for the upper bound (see Supp. Material 6 Table 1).

318

319 We also explored the effect of adding an uncertainty buffer to account for  
320 budget deviance from the baseline, following analyses on mega industry  
321 project management that highlights a 33% over-run cost for the majority of  
322 projects (Merrow 2013) (see Supp. Material 6 for detail).

323

## 324 **Cost estimate validation**

325 We conducted cost estimate validations for specific actions within TASs  
326 when cost data was available, by checking these estimates against  
327 information available in the scientific and grey literature, and/or through  
328 verifying with experts in threat management of the action being costed (see  
329 Supp. Material 7).

330

## 331 **Applying cost models to create spatial cost layers**

332 We created spatial layers at 1km<sup>2</sup> grid cells of the estimated costs of each  
333 TAS over its potential management area across Australia, a summation of

334 the spatially variable action and travel to site costs, excluding any continent-  
335 wide costs (Eq. 1 excluding non-spatial costs). All analyses were carried out  
336 in ArcGIS version 10.4 (Redlands 2016).

337

338 We accounted for spatial variation in actions in two ways: (i) the type of  
339 action suitable to the landscape (e.g. human population density, major  
340 vegetation type and occurrence of other threatened species) and (ii) the level  
341 of effort required to conduct the action (e.g. vegetation type and terrain  
342 ruggedness) (see Supp. Material 3 for detail).

343

344 To create the spatial cost layers for each action, we intersected the models  
345 with spatial information that determined the cost estimates to capture the  
346 spatial variation in efforts and costs over the potential management area. The  
347 action cost layers reflect the approximate effort that is needed in each 1km<sup>2</sup>  
348 grid cell, rather than prescribing detailed local scale actions. For each grid  
349 cell, we summed of the number of annualized trips required for the  
350 corresponding actions within a strategy, forming a spatial travel cost layer.  
351 These travel cost layers differed by land, air, and poison transport (see Supp.  
352 Material 3) that were calculated using a time to city map and the closest  
353 airport (see Supp. Material 8).

354

355 All spatial action cost and travel layers were clipped to the extent of the  
356 relevant threat (see Supp. Material 8), and for actions with no available or  
357 relevant threat layer, we presented the layers at the national scale (e.g.  
358 Invasive/Problematic Bird Management). The cost of each TAS was then  
359 calculated by adding the cost layers for each action involved in the TAS,  
360 including the relevant modes of transport (see Supp. Material 8).

## 361 **Results**

### 362 **Cost estimates for Threat Abatement Strategies**

363 We defined a total of 18 strategies that aimed to address key threats to  
364 Australia's biodiversity and estimated the action costs split by Labour, Travel  
365 within site, Consumables and Equipment (detailed estimates in Supp.  
366 Material 9, summarised at the TAS level in Table 3).

367  
368 More complex TASs required a higher number of actions (Table 3) due to  
369 addressing multiple threats (e.g., Invasive Fish Management has Tilapia and  
370 Trout across different river types) and multiple management requirements  
371 (e.g., Grazing Management required liaison with landowners, land and  
372 waterway fencing). There were 52 actions across the TASs, with some  
373 actions that were common across the TASs. Policy was the most common  
374 continent-wide action across 6 TASs, with other non-spatial actions including  
375 refugia mapping in Map Refugia, liaison in Grazing Management, extent  
376 mapping in Forestry Management, and Biosecurity. The remaining actions  
377 were largely unique to each TAS, except for the ground shooting action that  
378 applied to Invasive Predator Management, Large Invasive Herbivore  
379 Management, Native Herbivore Management and Invasive Rabbit  
380 Management, and the key habitat fencing action that applied to Native  
381 Herbivore management and Grazing Management (see Supp. Material 9).

382  
383 The annualised spatial cost estimates of Threat Abatement Strategies ranged  
384 from \$25/km<sup>2</sup> (\$0.25/ha) for the cheapest strategy of Map Refugia to  
385 \$0.88m/km<sup>2</sup> (\$8.8k/ha) for the most expensive strategy of Habitat Restoration  
386 in Rainforests (Table 3, see Supp. Material 11 for more detail). Cost  
387 estimates of TASs varied depending on the underlying action type and effort  
388 required, influenced by characteristics like action suitability, environment  
389 type, vegetation type and human population density (see Supp. Material 3).  
390

391 The continent-wide costs were estimated for efforts that pertained across  
392 Australia but were centrally carried out and independent of specific areas.  
393 The highest non-spatial costs were estimated for Biosecurity was \$932m  
394 (Table 3) that was largely adapted from the reported and recommended  
395 spending from the Australian biosecurity enquiry (Craik, Palmer & Sheldrake  
396 2017) (see Supp. Material 2). Map Refugia was costed non-spatially but  
397 applied per species, and the total cost of this strategy when applied can be  
398 multiplied by number of species that need this TAS (i.e. 10 species would  
399 require  $10 * \$13,899$ ).

400 Table 3. The range of annualised PV cost per unit estimated for each Threat Abatement Strategy summed across the management  
 401 actions (“number of actions”), compared across all possible cost variation scenarios (“# cost variation scenarios”), where costs could  
 402 vary by topographic resistance level (low, medium and high) and the spatially varying types and costs of management actions (i.e.  
 403 aerial vs ground, vegetation type, intactness, etc.). We show the median, minimum, and maximum cost, and the mode, or the most  
 404 common cost of each TAS across Australia (“most common across Australia”), determined from the highest proportion of projected  
 405 threat management area at a national level. Hydrology management was costed per instream structure, invasive fish management  
 406 and fencing for riparian zones in Grazing management was costed per km of waterway, and when not specified the remaining were  
 407 costed per km<sup>2</sup> area. Any non-spatial estimated costs were also displayed separately as “continent-wide”, these were either entire  
 408 Threat Abatement Strategies (i.e. Biosecurity) or the non-spatial component associated with the Threat Abatement Strategy (i.e.  
 409 policy component within Habitat Restoration). There was a non-spatial component for Map Refugia that was costed per species.

<b>Cost across cost variation scenarios</b>								
<b>#</b>	<b>Threat Abatement Strategy</b>	<b>Unit for costing</b>	<b>Number of actions</b>	<b># cost variation scenarios</b>	<b>Median</b>	<b>Minimum</b>	<b>Maximum</b>	<b>Most Common Across Australia</b>

410

411 **The proportion of budget for each cost component**

412 The proportion of TAS budgets that were estimated to be required for each  
413 cost component were, on average, Labour (49%), Travel within site (13%),  
414 Consumables (37%) and Equipment (2%). However, these proportions  
415 differed across TASs (Fig. 2). Actions such as Hydrology management, Map  
416 Refugia, Critical Sites Access Management, Forestry management were very  
417 labour intensive and required relatively minimal consumables apart from  
418 accommodation and meals. Others were more evenly balanced between  
419 labour and consumables such as Native Herbivore Management (bullets),  
420 Invasive Predator Management (baits), Invasive/Problematic Bird  
421 Management (bullets and nest-boxes), Ecological Fire Management (petrol  
422 for burning and water refills), and Invasive Rabbit Management (viral and bait  
423 supplies) (Fig. 2). Some TASs required consumables that outweighed other  
424 cost components, like materials for Habitat Restoration, fencing for Grazing  
425 Management, and the phosphide application for Phytophthora management  
426 (Fig. 2).

428

429 Figure 2. The cost component composition of each Threat Abatement Strategy displayed for the most common management option  
 430 (determined from the highest proportion of projected threat management area at a national level), sorted by decreasing proportion of  
 431 labour. We include spatial costs (any non-spatial costs were excluded).

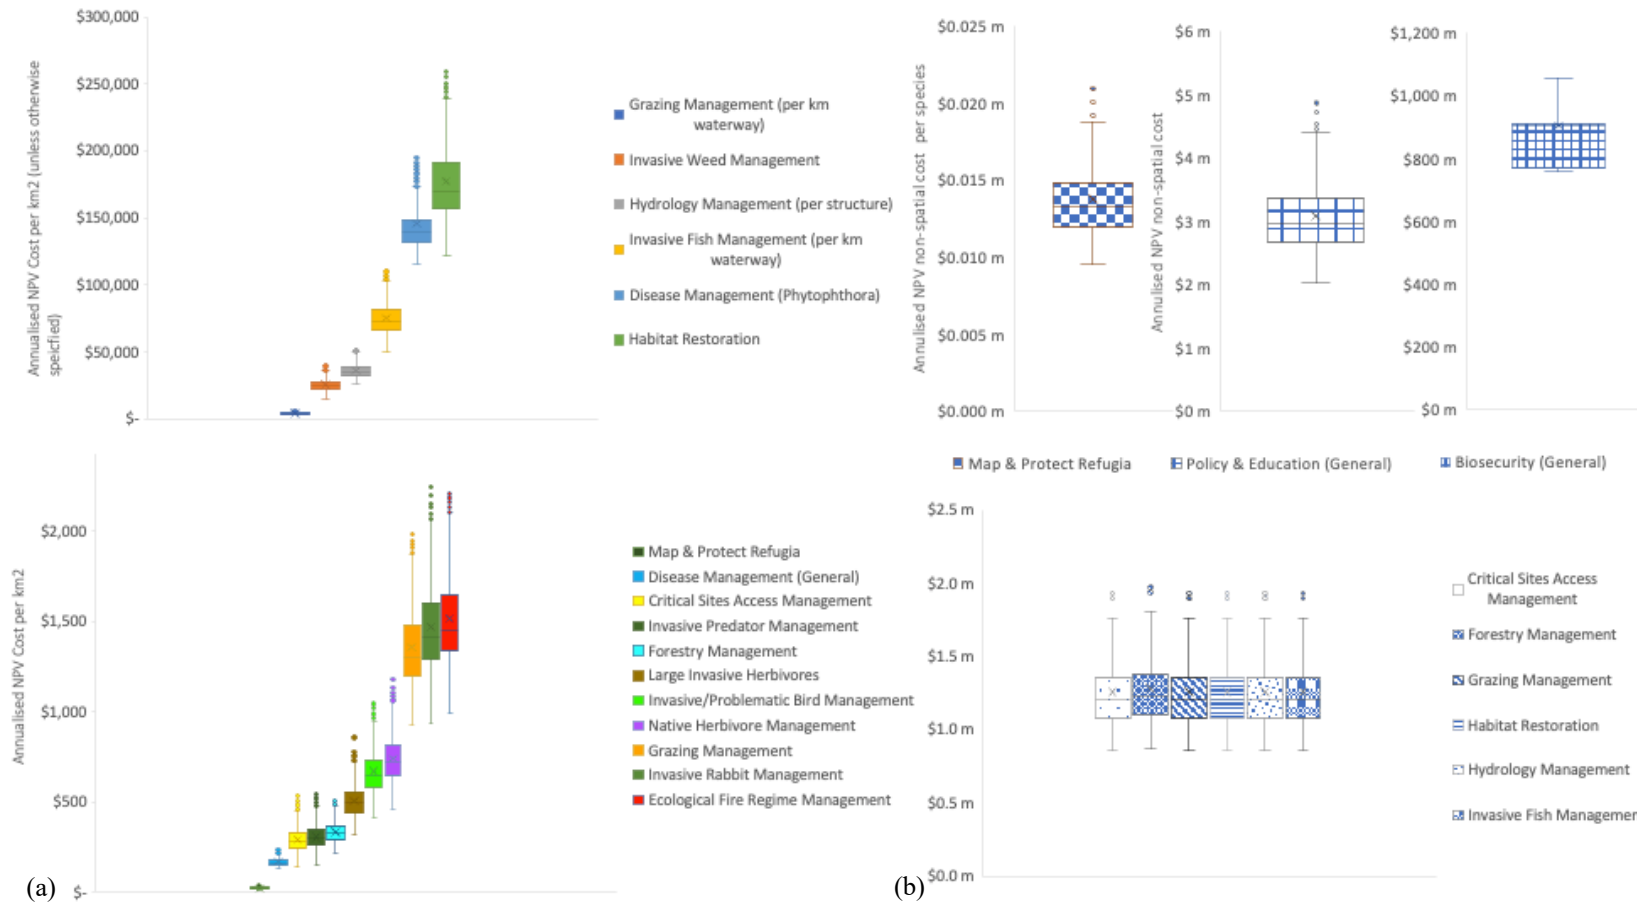

## 432 **Uncertainty in Cost estimates**

433 We estimated the impact of uncertainty for the TAS cost estimates by investigating how costs  
434 changed over 17 global input variables and including an uncertainty multiplier (Fig. 3). The  
435 overall relative distance of the lower and upper bound of TAS estimates from the baseline were  
436 -34% and 55% (Supp. Material 6 Table 2). Labour intensive TASs demonstrated higher relative  
437 uncertainty, as the global variables in the analysis mostly related to labour. The three most  
438 uncertain TAS cost estimates were for Map Refugia (-62%, +116%), Critical Sites Access (-  
439 51%,+84%) and Invasive Predator Management (-50%,+77%) (Supp. Material 6 Table 2).

440

441 Threat Abatement Strategies with higher cost/km<sup>2</sup> had a higher absolute variation in cost  
442 estimates under uncertain global parameters. For example, the cost estimate for Habitat  
443 Restoration ranged from \$122k to \$259k per km<sup>2</sup> (a difference of \$137k) with % variation from  
444 the baseline (-31%,+46%), and Phytophthora Management had the second highest absolute  
445 range in values from \$115k to \$195k per km<sup>2</sup> (a difference of \$80k) with relative distance from  
446 baseline (-21%,+34%) (Fig. 3 and Supp. Material 6 Table 2)

447  
 448 Figure 3 (a) and (b). An uncertainty analysis (N=1000) performed on discrete probability distributions of 18 global variables (Supp.  
 449 Material 6) reveals the range of annualised NPV costs for each Threat Abatement Strategy (TAS), including: (a) spatially variable  
 450 costs using the baseline (mode) cost value, determined from the highest proportion of projected threat management area at a  
 451 national level), and b) the baseline total Australia-wide cost for strategies without spatial variation. Box plots show the median, the  
 452 quartiles and interquartile ranges, with the mean marked with an X and the outliers with dots. The chart groupings were determined  
 453 by the axis range of costs of each TAS.

454 **Spatial variation in the costs of actions**

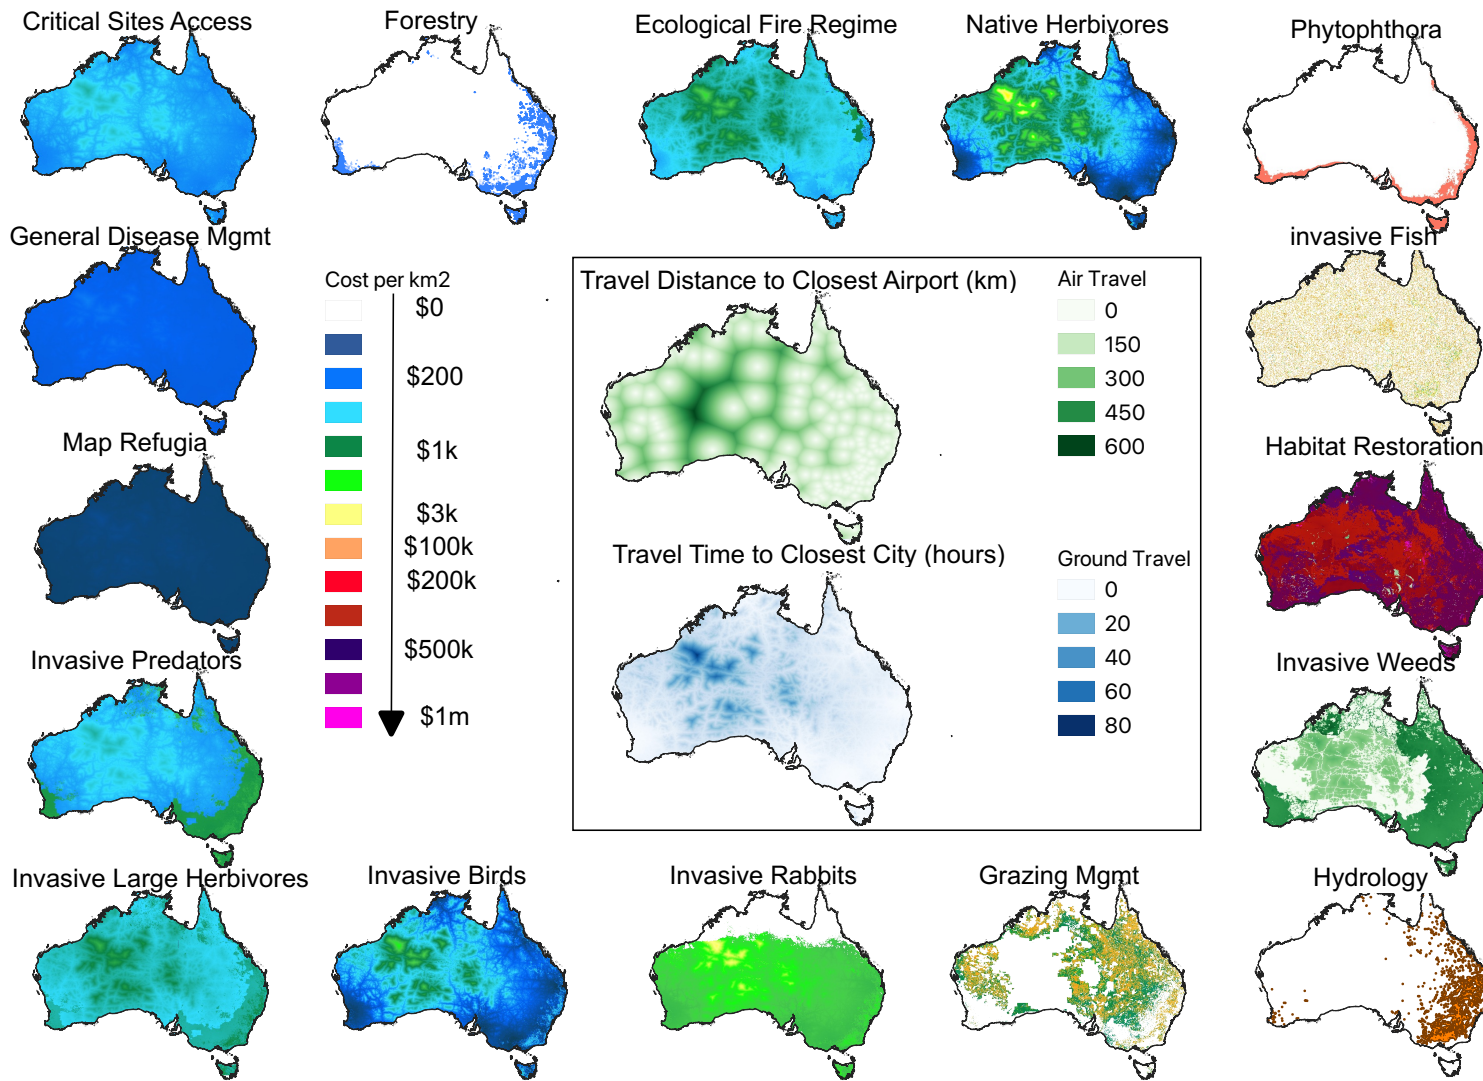

455 The cost of implementing a TAS at a location was a summation of the contributing action costs,  
456 accounting for spatial variables at the location (vegetation type, terrain ruggedness, action  
457 suitability, etc.) and including the travel to site cost (distance from the closest city or airport)  
458 (see Supp. Material 3 for detail). Excluding continent-wide non-spatial actions and TASs  
459 (Biosecurity and Policy and liaison only had continent-wide actions), we projected 16 TAS costs  
460 across the threat range or Australia-wide if there was no specific threat range, with the cost  
461 estimates including travel to site costs being \$24 - \$1.02m /km<sup>2</sup> (Fig. 4, see Supp. Material 10  
462 for individual spatial cost maps).

463  
464 The costs of Threat Abatement Strategies with fewer or less impactful spatial variables were  
465 relatively consistent throughout Australia, such as Map Refugia (\$24 - \$72/km<sup>2</sup>) where the only  
466 spatially variable action was ground surveys that varied by terrain ruggedness and travel to site  
467 costs. In contrast Large Invasive herbivore management (\$0 - \$255/km<sup>2</sup>) included divergent  
468 cost estimates for aerial and on-ground actions that were prescribed at a location depending  
469 upon the suitability of each action, and Grazing management (\$0- \$7460/km<sup>2</sup>), which includes  
470 different fencing costs at each location depending upon whether riparian zones fencing was  
471 prescribed (Fig. 4).

472  
473 TASs with higher management costs per unit were often associated with smaller management  
474 areas or limited threat ranges. For example, Habitat Restoration has high costs (mode of  
475 \$176k/km<sup>2</sup>) driven by the relatively large labour effort required for the regeneration of an area,  
476 but only projected across a smaller management area (1.6% of Australia) (Fig. 4). Similarly,  
477 Phytophthora management has a high cost/km<sup>2</sup> (mode of \$140k/km<sup>2</sup>) and a small range of  
478 9.3% of Australia. In contrast, Ecological Fire Regimes and Invasive Rabbit management have  
479 lower associated management costs (mode of \$1,464/km<sup>2</sup> and \$1,426/km<sup>2</sup>) but are projected  
480 over a large extent of Australia (100% and 82%) (Fig. 4). The exception was Invasive Weed  
481 Management that had a moderate to high cost per km<sup>2</sup> (mode of \$24.5k/km<sup>2</sup>) but was required  
482 across a broad range of Australia (64%).

483  
484 Travel costs were generally higher in the central-west of Australia, and for strategies with the  
485 lower labour, consumable and equipment costs, the travel cost in these regions represented a

486 larger proportion of overall costs (TASs on the left half of Fig. 4). For TASs with action costs  
487 that had low spatial variation the travel to site costs represented the source of overall cost  
488 variation. For example, for Disease management and Invasive Rabbit management, expensive  
489 pockets occur in remote areas due to travel to site and viral consumable costs increasing by up  
490 to ~2 fold (Supp. Material 12). For higher cost/km<sup>2</sup> TASs, the travel to site costs were not as  
491 visible due to the lower contributing proportions. For example, Invasive Weed Management had  
492 a labour-intensive weeding action cost that out shadowed the “remoteness” travel to site cost,  
493 with the spatial variation instead driven mostly by intactness and aridity (Supp. Material 12).

494  
 495 Figure 4. The spatial cost layers for 16 spatially variable Threat Abatement Strategies that include the travel time to site (inset  
 496 ground travel time and air travel distance) projected to threat range or Australia-wide if there was no pre-determined threat range.

## 497 **Discussion**

498 We provide a novel threat abatement budgeting tool for estimating the costs  
499 of a comprehensive set of generic threat management strategies impacting  
500 biodiversity across Australia. The cost estimates and approaches for applying  
501 them are transparent and updatable, allowing for continual improvements in  
502 conservation planning that is better informed by knowledge of threat  
503 management costs. Our approach builds on existing information focussed on  
504 the actions and resources required to abate threats to biodiversity (Brazill-  
505 Boast *et al.* 2018; DPIE 2021; Ward *et al.* 2021) and costing out threat  
506 abatement efforts at smaller spatial scales (Cattarino *et al.* 2018; Wenger *et*  
507 *al.* 2018; Carwardine *et al.* 2019; Thomson *et al.* 2020). The three outputs  
508 provided can help plan for on-ground management and inform decision-  
509 making across broader scales. First, a set of expert-derived assumptions that  
510 define the 18 TASs. Secondly, a mechanistic cost model for each strategy  
511 that can be applied or modified to suit the locally determined locations and  
512 extent of management. Third, spatially variable TAS cost maps that can  
513 estimate management effort across large scales.

514  
515 Our models show that the cost of managing a threat to biodiversity across  
516 Australia are likely to vary from \$24 - \$1.02m /km<sup>2</sup>, depending on the TAS  
517 required, the travel distance to site and the site characteristics. Our per km<sup>2</sup>  
518 cost estimates were similar or higher than cost estimates from previous  
519 analyses, which is likely due to the comprehensive inclusion of all cost  
520 components in our cost models, including planning, travel to site and labour  
521 on-costs (see Supp. Material 7).

522  
523 Improving the use of consistent standardised financial reporting is important  
524 for the effectiveness of the conservation sector (Cook *et al.* 2017; Iacona *et*  
525 *al.* 2018). Current conservation investments largely occur without reliable  
526 information on the costs of how the investment will be spent, and  
527 conservation expenditure is typically not recorded in ways that can improve

528 current knowledge of conservation costs. The bottom-up costing model  
529 structure we provide can inform, and be improved by, the collection of  
530 additional cost information. By consistently recording the costs of  
531 individualised components of threat abatement activities, it becomes possible  
532 to understand the make-up of a total strategy cost and leverage these  
533 estimate costs elsewhere.

534

535 The collection of improved data on conservation expenditure should be used  
536 to improve the accuracy and precision in the presented cost models. Our  
537 uncertainty analysis indicated our estimates had a range of (-34%, +55%) for  
538 the baseline TAS values, and this variation needs to be accounted for when  
539 applying the cost estimates. We modified only global parameters, and further  
540 investigation of action specific parameters could reveal other parameters  
541 influencing cost estimates. A value of information (Vol) analysis approach  
542 estimates the higher expected payoff from better decision making as a result  
543 of reducing uncertainty (Raiffa & Schlaifer 1961), and Vol analyses are only  
544 just gaining traction in the realm of conservation decision making (Bolam *et*  
545 *al.* 2019). A Vol analysis can help prioritise the collection of improved  
546 information for the parameters which influence the cost estimates and  
547 subsequent management investment decisions.

## 548 **Conclusion**

549 Every year billions of dollars are spent on conservation management  
550 worldwide (Waldron *et al.* 2013). This expenditure largely occurs without a  
551 priori estimates of conservation management costs across broad scales and  
552 is not recorded in ways that can inform future conservation management  
553 budgets and analyses comparing the relative cost-effectiveness of actions.  
554 Our work provides new guidance on consistent approaches for estimating,  
555 recording, and informing cost estimates that can be built on or adapted with  
556 additional information from local to national scales. We aim to enable the  
557 conservation industry to match other sectors in articulating the investment  
558 required to achieve its sought goals. By continuing to progress knowledge on

559 the costs of managing threats to biodiversity, more strategic revenue raising  
560 and improved use of available resources to achieve conservation outcomes  
561 are possible.

## 562 **Author Contributions**

563 CY, JW, MW, AR, JC conceived the ideas and design methodology; CY  
564 collected the data with contribution and direction from SvL, SL, WG, SS, ML,  
565 and MK. CY and MW analysed the data; CY, JW and JC led the writing of the  
566 manuscript. All authors contributed critically to the drafts and gave final  
567 approval for publication.

## 568 **Acknowledgements**

569 The cost estimates and modelling approach were co-developed through  
570 expert input during two online workshops and follow-up discussions in 2020-  
571 2021, involving the co-authors and additional participants (see Supp. Material  
572 13).
