47 Abstract

- 1. Budgeting for biodiversity conservation requires realistic estimates of 48 49 the costs of threat abatement. However, data on the costs of 50 managing threats to biodiversity is often unavailable or unable to be 51 extrapolated across relevant locations and scales due to a lack of 52 transparency and consistency in how it was collated. Conservation 53 expenditure largely occurs without a priori estimates costs across 54 broad scales and is not recorded in ways that can inform future 55 budgets nor the comparison of action cost-effectiveness.
- 56 2. We provide transparent, broadly applicable cost models for 18 Threat 57 Abatement Strategies aimed at managing the processes threatening 58 biodiversity across the Australian continent. We define the actions 59 required to implement each strategy and use a consistent structure to 60 classify costs into components of labour, travel, consumables and 61 equipment. We drew upon expert knowledge and literature to 62 parameterise and apply each model, estimating the implementation 63 cost of each strategy across Australia, accounting for spatial variables 64 such as threats, terrain, and travel distance.
- 65 3. The baseline cost estimates generated by the models for threat 66 abatement strategies varied considerably between strategies and 67 across Australia, ranging from \$24 - \$0.88m per km²/year (\$0.24 -68 \$8.8k per ha/year). Across all strategies, Labour made up most of the 69 action costs (49%), followed by Consumables (37%), Travel (13%) 70 and Equipment (2%). A Monte Carlo simulation indicated that threat 71 abatement strategy costs had on average an upper and lower bound 72 of +44% and -33% of the baseline cost.
- Policy Implications We provide a consistent and transparent
 approach to budgeting for threat abatement strategies, aiming to
 improve conservation planning processes, outcomes and reporting
 requirements across Australia. Understanding the budget required to
 achieve threat management outcomes can aid revenue-raising and
 target setting. The models, cost layers and estimates we generate

- 79 provide the basis for a nationally consistent approach for estimating
- 80 and recording the cost of biodiversity management strategies, which
- 81 should be continually improved and updated over time.

86 Introduction

87 Understanding the financial resources required to manage threats and achieve conservation goals is important for budgeting, investigating value of 88 89 alternative actions, target-setting and prioritising limited conservation 90 resources (Cook et al. 2017; lacona et al. 2018). However, the costs of 91 implementing a conservation action are often challenging to estimate, and 92 most conservation investments occur without reliable estimates of their return 93 on investment (Auerbach, Tulloch & Possingham 2014). This is, in part, due 94 to the lack of readily applicable cost data available to the conservation sector 95 (lacona et al. 2018). Where conservation cost data are available it often lacks 96 critical information on how estimates are produced, and what is included and 97 excluded (Armsworth 2014). The influence of a cost layer in prioritisation can 98 be as high as the joint influence of thousands of species layers (Kujala et al. 99 2018), and absence of high quality cost data can be sub-optimal (Naidoo et 100 al. 2007; Carwardine et al. 2008) driving up to 35% loss of environmental 101 value benefits (Pannell & Gibson 2016).

102

103 Local and regional scale conservation budgeting tools (lacona et al. 2018; 104 Wenger et al. 2018; Thomson et al. 2020) can contribute to more accurate 105 project cost predictions (Cook et al. 2017), improve cost data collection 106 processes (lacona et al. 2018) and estimate the efficiency of delivering 107 conservation outcomes at the scale that the models have been applied 108 (Margoluis et al. 2009). However, estimates generated by these tools are not 109 generalisable for larger scale strategic planning that must occur across vast 110 areas and land tenures. Hence, cost estimates cannot easily be compared 111 across studies and applications, nor confidently extrapolated to other 112 locations (Cook et al. 2017; lacona et al. 2018). For example, while it is 113 possible to find one or more locations with accurate cost information for 114 managing weeds, we lack information on larger scale to strategically budget 115 at a regional or continental scale (Kearney *et al.* 2019). The knowledge gap 116 in the budget required to achieve a conservation outcome at the broad-scale 117 cannot easily be filled by combining multiple sources of local scale cost

- 118 estimates that have been derived using different approaches or delivery
- agents. Further effort is needed to build cost models and budgets applicable
- 120 across broad landscapes, with adjustable assumptions to enable transparent
- 121 comparisons of costs across different regions, actions and contexts.
- 122

123 Here we address this knowledge gap by developing and implementing a 124 systematic approach to model the costs of conservation threat abatement 125 strategies across Australia. Australia is a mega-biodiverse nation whose 126 biodiversity faces significant threatening processes over vast landscapes. 127 tenures and ecosystem types (Jackson 2016; Kearney et al. 2019). Building 128 on previous efforts (Wenger et al. 2018; Thomson et al. 2020), we developed 129 models that include a comprehensive range of actions, with underlying 130 assumptions assigned to the cost components of labour, travel, consumables 131 and equipment. We model generic and scalable actions, rather than 132 attempting to piece together cost information collected using different 133 approaches and locations. In doing so, we provide estimates of the costs of 134 abating 18 major threats to Australia's biodiversity, and a set of transferable, 135 transparent cost models and spatial cost layers that can used for planning 136 and prioritisation efforts at national and other broad scales. These estimates 137 are reflective of average efforts across broad landscape and assumptions 138 should be modified for finer resolution analyses where improved local scale 139 information exists.

140 Methodology

Our approach applies the best available national scale knowledge on threat 141 142 abatement for the benefit of biodiversity and builds upon existing approaches 143 for estimating the costs of threat abatement actions. We collated information 144 and methods on threat abatement actions and costs from the scientific and 145 grey literature, including Australian threat abatement plans (TAP), Australian 146 threat abatement advices and action plans, and available data and 147 approaches from two existing programs: the Saving our Species program in 148 NSW (DPIE 2021) and DELWP's Strategic Management Prospects in

- 149 Victoria (Thomson *et al.* 2020). We established a working group of 47
- 150 experts, with whom we developed strategies, actions and cost estimates at
- 151 two online workshops and discussions. Six of the experts are co-authors in
- 152 this paper and the complete list is provided in the acknowledgements.
- 153

154 We applied this knowledge and information to estimate the costs of threat 155 abatement strategies following three steps (Fig. 1). First, we described each 156 threat abatement strategy (hereafter, TAS), the actions involved to complete 157 each strategy over a 30-year time frame. Within each action (e.g. pre-action 158 office planning, aerial baiting, post-action valuation), we defined four cost 159 components: labour (L), travel within site (T), consumables (C) and 160 equipment (E) (Table 1) (see Supp. Material 4 for details). Second, we 161 structured generic models to estimate the cost of each strategy, as a function 162 of the contributing action costs (spatial and non-spatial) and travel to site 163 costs for all actions included in the strategy. Third, we extrapolated the 164 estimated action and travel costs across Australia to create spatial cost layers at 1km² resolution, using information on the locations of threats, 165 166 landscape resistance levels and travel time. We created spatial cost models 167 for each TAS separately for areas across Australia where the strategy is 168 likely to be relevant, based on available information about the spatial extent 169 of threats.

Define Threat Abatement Strategies (TAS) and actions

- Define actions, TAS and assumptions for cost components, through literature and expert consultation **Output 1: TAS assumptions**

Example of Invasive Predator TAS

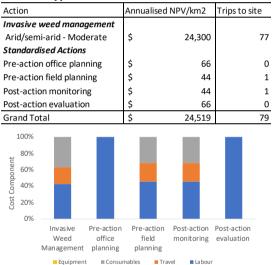

Annual aerial baiting:

- 1 FTE annually to administer bait from aircraft (Labour)
- 50 baits/km2 at \$0.50/bait delivered at 500m transects (Consumables)
- Sweating rack of \$15k to prepare baits (Equipment)
- Aircraft at \$850/hr for petrol and pilot flying at 130km/h with refueling distance of 400km and transit speed of 250km/h (Travel).
- Accommodation and food at \$210 per person per day (Consumables).
- Aircraft at \$880/hr (\$850+\$30 hourly travel compensation labour rate) for aircraft, pilot and person from the closest airport (Travel).

Model the costs of actions and strategies

Estimate cost/unit and trips required
 Discount, annualise and apply multipliers
 Output 2: Cost/km² per action and trips required per action

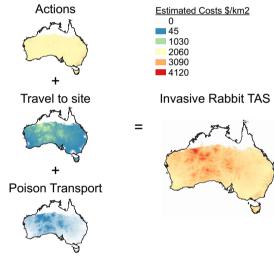

Example of invasive weed management TAS in a typical location

Create spatial cost layers for each strategy

- Create national cost layers based on cost/km², threats and resistance + travel cost layers based on trips required and travel_distance **Output 3: Cost and travel layers by TAS**

Example of invasive rabbit TAS

- 171 Figure 1. The three-step methodology overview to estimate costs for Threat Abatement Strategies (TASs). The broad steps are
- shown at the top row, the middle row summarises the generic methodology that applies to each TAS, and in the bottom row we
- 173 demonstrate the output of each step with an example.

Defining Threat Abatement Strategies and actions

175 We defined 18 strategies to abate the key threats to Australia's terrestrial and 176 freshwater biodiversity, using the current literature on the threats to 177 Australia's biodiversity and existing and future potential threat management 178 strategies. We worked with experts in biodiversity conservation and 179 management (see Acknowledgements) to define a Threat Abatement 180 Strategy (TAS) to abate each threat presented by Ward et al. (2021), who 181 define threats impacting Australia's EPBC listed threatened species (1,796 182 species). We assumed the threats impacting threatened species would be 183 relevant to the range of Australia's biodiversity. Where possible we grouped 184 threats of similar nature that could be abated under the same TAS (see 185 Supp. Material 1 for the assignment of TAS to the threats compiled by Ward 186 et al. (2021)).

187

188 For each strategy (detailed in Supp. Material 2) we defined the set of actions 189 involved throughout the planning, implementation, and evaluation process of 190 carrying out the strategy (adapted from (lacona et al. 2018; Wenger et al. 191 2018; Carwardine et al. 2019). The implementation actions were specific to 192 each strategy, however we defined four standardised actions that covered 193 the planning and evaluation stages for all threat abatement strategies: pre-194 action office planning, pre-action field planning, post-action monitoring and 195 post-action evaluation, and made general assumptions on the level of effort 196 required for each (Table 1).

197

We defined implementation actions generically, rather than attempting to prescribe site-specific details of actions, which would require more detailed local scale information. However, actions and their costs vary based on spatial variables like terrain ruggedness, vegetation type and human population density (see Supp. Material 3). All actions and strategies were considered over a 30-year time period, and we assigned a frequency of reoccurrence for each action (e.g. every "X" years over 30 years). We assumed

- 205 all actions are performed humanely, are undertaken by competent/skilled
- 206 practitioners that follow best practices, and that landholders and stakeholders
- are willing to participate.
- 208
- 209 Table 1. Standardised planning and evaluation actions that are included in
- each Threat Abatement Strategy, the general description of each, and the
- assumed effort required for each action and finally, the cost components
- 212 relevant to each action. These standardised actions are additional to the on-
- 213 ground implementation efforts involved with each strategy. The assumptions
- regarding amount of effort used was based on expert knowledge and grey
- and published literature (see Supp. Material 2).

216

218 Model the costs of actions and strategies

We designed a generic cost model structure that can be applied to eachthreat abatement strategy and used it to estimate the costs of each strategy.

221 The process of applying the cost models included estimating the action costs

- and travel to site costs associated with each strategy and conducting an
- 223 uncertainty analysis on the cost inputs to test their robustness.

224 Generic Cost Model

225 The total cost of a strategy within a management area is a function of its 226 spatial action costs, travel to site costs, and non-spatial costs (Equation 1), with the action costs per km² calculated as the sum of the cost components 227 228 (Equation 2), and the travel to site cost per km² determined by the cost of the 229 return trips required for each action (Equation 3). To account for efficiencies 230 of scale we typically assumed actions were carried out over a management area window of 100 km² (Table 2). The time horizon for each action, and 231 232 hence the cost models, is 30 years from 31st of December 2020 to 31st of 233 December 2050. We present all final cost estimates as an annualized cost of 234 the 30-year Present Value (PV) as at 31st of December 2020 accounting for 235 the frequency of actions and using a real discount rate of 4% and assuming constant real costs into the future (see Supp. Material 3 for detail). The 236 237 description of model parameters is shown in Table 2.

238

239
$$TAS cost = \sum_{actions} (Action cost per km^2 \times Action area)$$

240 $+ \sum_{actions} (Travel to site cost per km^2 per km distance)$
241 $\times Action area \times Distance to site \times 2)$

255		

Table 2. Cost model parameter description from Eq. 1, 2 and 3. 256

	Cost Model	
Equation	Parameter	Description
1	Action Cost unit	Per km ² unless specified otherwise, e.g. per km of
		river length or per in-stream structure.
1	Action area	Spatial extent of action, based on relevant threat
		layers
1	Distance to site	Distance to closest city/airport to each grid-cell,
		multiplied by 2 for return trip
1	Non-spatial costs (if	High level efforts that do not vary spatially, e.g.
	any)	policy and education
2	Annualised Cost	A Present Value (PV) was calculated for the costs
	components	accounting for different payment frequencies, then
		the PV was annualised over 30 years. The
		components included Labour (L), travel within site
		(T), consumables (C) and equipment (E)
2,3	Multipliers	30% for on-costs that are only applied to labour
		and 10% for on-site contingencies that only apply

		to costs that are incurred on-site. These can be
		adjusted by the end-user.
1,2,3	Management grid	Standard management area of 100km ² unless
	window size	specified otherwise e.g. per 100km waterway or
		per instream structure
3	Number of trips	Visits required for onsite action to be completed in
		multiples of 21-day periods of field work
3	Annualised Travel	Cost per hour includes vehicle cost and time
	cost	compensation cost for personnel. A PV was
		calculated for the costs accounting for different
		payment frequencies, then the PV was annualised

over 30 years.

257

258 For each action we calculated the aggregate present value of costs over 30

259 years and converted the result to an equivalent annual value (an annuity).

Using the standard annuity due formula (Chan & Tse 2017) (Equation 4),

261 cash flows were first calculated as a PV across the time horizon adapted for

the differing payment frequencies (Equation 5), then the PV values were

annualised using the standard annuity due formula (Equation 4). This allowed

264 cash flows to be consistent and additive across all actions and strategies.

265

266
$$\ddot{a}_n = P x \frac{1 - (1+i)^{-n}}{i} x (1+i)$$

267

(4)

Where \ddot{a}_n is the annuity due at time zero for *n* payments, *P* is the regular cash flow incurred from period 0 to period n - 1, and *i* is the real discount rate.

271
$$\ddot{a}_{rk} = P x \frac{1 - (1 + I)^{-rk}}{I} x (1 + I)$$

272 (5)

- 273 Where \ddot{a}_{rk} is the annuity due at time zero for *r* repayments that occur at the
- start of every k periods such that n = rk, and the adapted real discount rate I
- 275 across the *k* periods such that $(1 + I) = (1 + i)^k$
- 276

277 We included two cost multipliers, which were combined multiplicatively to 278 each relevant cost component. For labour on-costs, we applied a 30% 279 multiplier to Labour costs based on the on-cost percentages used for 280 professional staff at the University of New South Wales in NSW and ACT 281 (HR 2018b; HR 2018a) and on-costs applied to action costs in South Africa 282 (van Wilgen et al. 2016). On-costs account for employee support, office 283 space and IT equipment, insurance, superannuation and leave, etc. For on-284 site contingencies, a 10% multiplier was applied to Labour, Travel and 285 Consumable cost components for on-site based work, to account for 286 unforeseen circumstances like bad weather and logistical and operational 287 challenges. The 10% was chosen based on the collective advice of the 288 expert group.

289 Action and travel to site costs

290 Based on the model assumptions (see Supp. Material 3) and cost component 291 assumptions (see Supp. Material 4), we modelled the action costs within 292 each TAS at the relevant unit of measurement (Eq. 2) (see Supp. Material 5). 293 The relevant unit of measurement was typically per km², with management 294 actions that occurred along a waterway estimated per km of waterway length 295 (e.g. waterway fencing in Grazing Management TAS, Trout Barrier 296 Installation in Invasive fish management TAS), and management actions that 297 occurred for Hydrology TAS were estimated per in-stream structure (see 298 Supp. Material 2 & 5). We converted the PV costs for each action to an 299 equivalent annual value (see annuity calculation above). We then divided all 300 the costs by the standardised area to calculate a per unit of measurement 301 and applied the corresponding cost multipliers for the relevant cost 302 components. We estimated the Travel to site costs per km² per unit area (Eq. 303 3) driven by the mode of transport, travel distance and the number of trips

required (for detail see Supp. Material 3 for cost models see Supp. Material5).

306 Uncertainty in Costs

307 We conducted a Monte Carlo analysis to represent the uncertainty around 308 the cost inputs. We created probability distributions for global variables that 309 were common across the TASs and these were often labour related, and 310 uncertainty of action-specific variables were not included i.e. bait costs, bullet 311 costs etc. We assume that the cost estimates generated from our cost inputs 312 represent our baseline estimates that correspond to the median value (50th 313 percentile), we then subjectively set values for the lower bound and upper bound values that correspond to the 10th and 90th percentile. We created 314 315 individual probability distributions for 18 parameter values that were common 316 across the TASs, with a 25% probability for the lower bound, 50% for the 317 baseline values and 25% for the upper bound (see Supp. Material 6 Table 1). 318 319 We also explored the effect of adding an uncertainty buffer to account for

320 budget deviance from the baseline, following analyses on mega industry

321 project management that highlights a 33% over-run cost for the majority of

322 projects (Merrow 2013) (see Supp. Material 6 for detail).

323

324 Cost estimate validation

325 We conducted cost estimate validations for specific actions within TASs

326 when cost data was available, by checking these estimates against

327 information available in the scientific and grey literature, and/or through

- verifying with experts in threat management of the action being costed (seeSupp. Material 7).
- 330

331 Applying cost models to create spatial cost layers

332 We created spatial layers at 1km² grid cells of the estimated costs of each

333 TAS over its potential management area across Australia, a summation of

the spatially variable action and travel to site costs, excluding any continentwide costs (Eq. 1 excluding non-spatial costs). All analyses were carried out
in ArcGIS version 10.4 (Redlands 2016).

337

We accounted for spatial variation in actions in two ways: (i) the type of action suitable to the landscape (e.g. human population density, major vegetation type and occurrence of other threatened species) and (ii) the level of effort required to conduct the action (e.g. vegetation type and terrain ruggedness) (see Supp. Material 3 for detail).

343

344 To create the spatial cost layers for each action, we intersected the models 345 with spatial information that determined the cost estimates to capture the 346 spatial variation in efforts and costs over the potential management area. The 347 action cost layers reflect the approximate effort that is needed in each 1km² 348 grid cell, rather than prescribing detailed local scale actions. For each grid 349 cell, we summed of the number of annualized trips required for the 350 corresponding actions within a strategy, forming a spatial travel cost layer. 351 These travel cost layers differed by land, air, and poison transport (see Supp. 352 Material 3) that were calculated using a time to city map and the closest 353 airport (see Supp. Material 8). 354

355 All spatial action cost and travel layers were clipped to the extent of the

relevant threat (see Supp. Material 8), and for actions with no available or

357 relevant threat layer, we presented the layers at the national scale (e.g.

358 Invasive/Problematic Bird Management). The cost of each TAS was then

359 calculated by adding the cost layers for each action involved in the TAS,

including the relevant modes of transport (see Supp. Material 8).

361 **Results**

362 Cost estimates for Threat Abatement Strategies

We defined a total of 18 strategies that aimed to address key threats to Australia's biodiversity and estimated the action costs split by Labour, Travel

365 within site, Consumables and Equipment (detailed estimates in Supp.

366 Material 9, summarised at the TAS level in Table 3).

367

368 More complex TASs required a higher number of actions (Table 3) due to 369 addressing multiple threats (e.g., Invasive Fish Management has Tilapia and 370 Trout across different river types) and multiple management requirements 371 (e.g., Grazing Management required liaison with landowners, land and 372 waterway fencing). There were 52 actions across the TASs, with some 373 actions that were common across the TASs. Policy was the most common 374 continent-wide action across 6 TASs, with other non-spatial actions including 375 refugia mapping in Map Refugia, liaison in Grazing Management, extent 376 mapping in Forestry Management, and Biosecurity. The remaining actions 377 were largely unique to each TAS, except for the ground shooting action that 378 applied to Invasive Predator Management, Large Invasive Herbivore 379 Management, Native Herbivore Management and Invasive Rabbit 380 Management, and the key habitat fencing action that applied to Native 381 Herbivore management and Grazing Management (see Supp. Material 9). 382 383 The annualised spatial cost estimates of Threat Abatement Strategies ranged from \$25/km² (\$0.25/ha) for the cheapest strategy of Map Refugia to 384

385 \$0.88m/km² (\$8.8k/ha) for the most expensive strategy of Habitat Restoration

in Rainforests (Table 3, see Supp. Material 11 for more detail). Cost

387 estimates of TASs varied depending on the underlying action type and effort

388 required, influenced by characteristics like action suitability, environment

type, vegetation type and human population density (see Supp. Material 3).

- 391 The continent-wide costs were estimated for efforts that pertained across
- 392 Australia but were centrally carried out and independent of specific areas.
- 393 The highest non-spatial costs were estimated for Biosecurity was \$932m
- 394 (Table 3) that was largely adapted from the reported and recommended
- 395 spending from the Australian biosecurity enquiry (Craik, Palmer & Sheldrake
- 396 2017) (see Supp. Material 2). Map Refugia was costed non-spatially but
- 397 applied per species, and the total cost of this strategy when applied can be
- 398 multiplied by number of species that need this TAS (i.e. 10 species would
- 399 require 10*\$13,899).

400 Table 3. The range of annualised PV cost per unit estimated for each Threat Abatement Strategy summed across the management actions ("number of actions"), compared across all possible cost variation scenarios ("# cost variation scenarios"), where costs could 401 402 vary by topographic resistance level (low, medium and high) and the spatially varying types and costs of management actions (i.e. aerial vs ground, vegetation type, intactness, etc.). We show the median, minimum, and maximum cost, and the mode, or the most 403 common cost of each TAS across Australia ("most common across Australia"), determined from the highest proportion of projected 404 405 threat management area at a national level. Hydrology management was costed per instream structure, invasive fish management and fencing for riparian zones in Grazing management was costed per km of waterway, and when not specified the remaining were 406 407 costed per km² area. Any non-spatial estimated costs were also displayed separately as "continent-wide", these were either entire 408 Threat Abatement Strategies (i.e. Biosecurity) or the non-spatial component associated with the Threat Abatement Strategy (i.e. 409 policy component within Habitat Restoration). There was a non-spatial component for Map Refugia that was costed per species.

Cost across cost variation scenarios

#	Threat Abatement Strategy	Unit for costing	Number of actions	# cost variation scenarios	Median	Minimum	Maximum	Most Common Across Australia
1	Biosecurity	Continent- wide	1	1	\$931,770,000	-	-	-

The proportion of budget for each cost component

412 The proportion of TAS budgets that were estimated to be required for each 413 cost component were, on average, Labour (49%), Travel within site (13%), 414 Consumables (37%) and Equipment (2%). However, these proportions 415 differed across TASs (Fig. 2). Actions such as Hydrology management, Map 416 Refugia, Critical Sites Access Management, Forestry management were very 417 labour intensive and required relatively minimal consumables apart from 418 accommodation and meals. Others were more evenly balanced between 419 labour and consumables such as Native Herbivore Management (bullets), 420 Invasive Predator Management (baits), Invasive/Problematic Bird 421 Management (bullets and nest-boxes), Ecological Fire Management (petrol 422 for burning and water refills), and Invasive Rabbit Management (viral and bait 423 supplies) (Fig. 2). Some TASs required consumables that outweighed other 424 cost components, like materials for Habitat Restoration, fencing for Grazing 425 Management, and the phosphide application for Phytophthora management 426 (Fig. 2).

429 Figure 2. The cost component composition of each Threat Abatement Strategy displayed for the most common management option

- 430 (determined from the highest proportion of projected threat management area at a national level), sorted by decreasing proportion of
- 431 labour. We include spatial costs (any non-spatial costs were excluded).

432 Uncertainty in Cost estimates

- We estimated the impact of uncertainty for the TAS cost estimates by investigating how costs changed over 17 global input variables and including an uncertainty multiplier (Fig. 3). The overall relative distance of the lower and upper bound of TAS estimates from the baseline were -34% and 55% (Supp. Material 6 Table 2). Labour intensive TASs demonstrated higher relative uncertainty, as the global variables in the analysis mostly related to labour. The three most uncertain TAS cost estimates were for Map Refugia (-62%, +116%), Critical Sites Access (-51%,+84%) and Invasive Predator Management (-50%,+77%) (Supp. Material 6 Table 2).
- 141 Threat Abatement Strategies with higher cost/km² had a higher absolute variation in cost
- estimates under uncertain global parameters. For example, the cost estimate for Habitat
- Restoration ranged from \$122k to \$259k per km² (a difference of \$137k) with % variation from
- the baseline (-31%,+46%), and Phytophthora Management had the second highest absolute
- range in values from \$115k to \$195k per km² (a difference of \$80k) with relative distance from
- baseline (-21%,+34%) (Fig. 3 and Supp. Material 6 Table 2

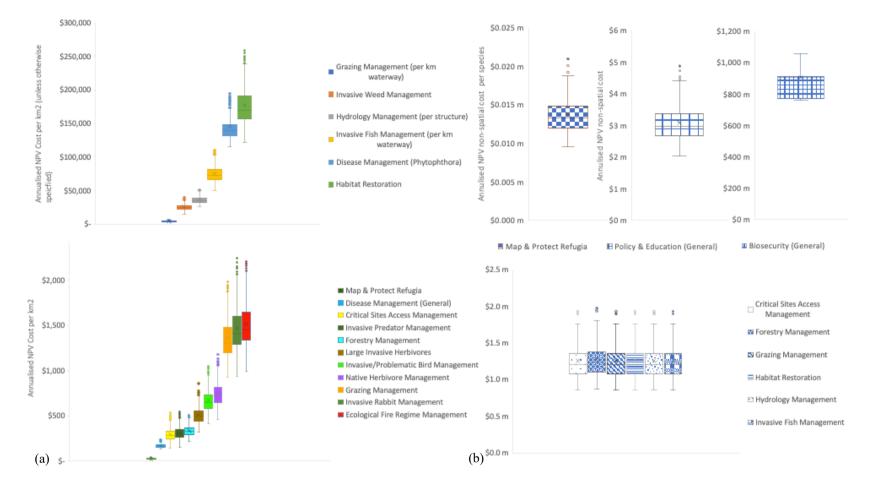

Figure 3 (a) and (b). An uncertainty analysis (N=1000) performed on discrete probability distributions of 18 global variables (Supp. Material 6) reveals the range of annualised NPV costs for each Threat Abatement Strategy (TAS), including: (a) spatially variable costs using the baseline (mode) cost value, determined from the highest proportion of projected threat management area at a national level), and b) the baseline total Australia-wide cost for strategies without spatial variation. Box plots show the median, the quartiles and interquartile ranges, with the mean marked with an X and the outliers with dots. The chart groupings were determined by the axis range of costs of each TAS.

454 Spatial variation in the costs of actions

455 The cost of implementing a TAS at a location was a summation of the contributing action costs, 456 accounting for spatial variables at the location (vegetation type, terrain ruggedness, action 457 suitability, etc.) and including the travel to site cost (distance from the closest city or airport) 458 (see Supp. Material 3 for detail). Excluding continent-wide non-spatial actions and TASs 459 (Biosecurity and Policy and liaison only had continent-wide actions), we projected 16 TAS costs 460 across the threat range or Australia-wide if there was no specific threat range, with the cost estimates including travel to site costs being \$24 - \$1.02m /km² (Fig. 4, see Supp. Material 10 461 462 for individual spatial cost maps).

463

464 The costs of Threat Abatement Strategies with fewer or less impactful spatial variables were 465 relatively consistent throughout Australia, such as Map Refugia (\$24 - \$72/km²) where the only spatially variable action was ground surveys that varied by terrain ruggedness and travel to site 466 467 costs. In contrast Large Invasive herbivore management (\$0 - \$255/km²) included divergent 468 cost estimates for aerial and on-ground actions that were prescribed at a location depending 469 upon the suitability of each action, and Grazing management (\$0- \$7460/km²), which includes 470 different fencing costs at each location depending upon whether riparian zones fencing was 471 prescribed (Fig. 4).

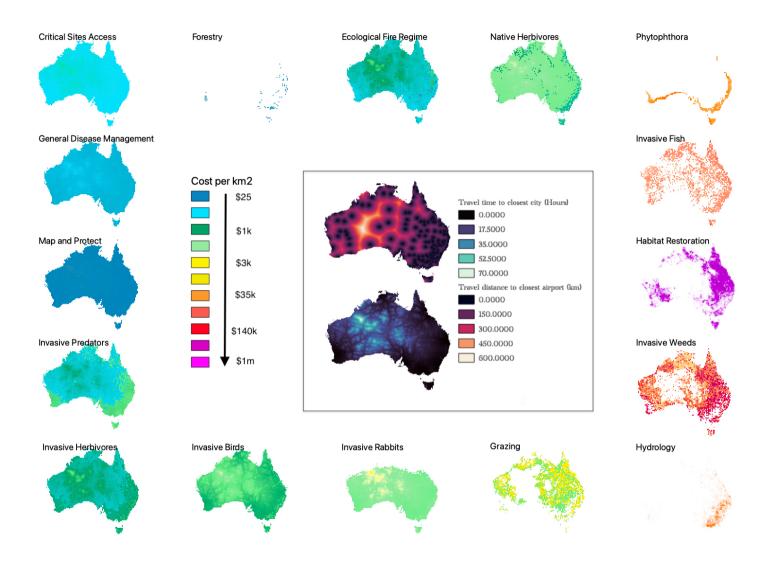

472

473 TASs with higher management costs per unit were often associated with smaller management 474 areas or limited threat ranges. For example, Habitat Restoration has high costs (mode of 475 \$176k/km²) driven by the relatively large labour effort required for the regeneration of an area, 476 but only projected across a smaller management area (1.6% of Australia) (Fig. 4). Similarly, Phytophthora management has a high cost/km² (mode of \$140k/km²) and a small range of 477 478 9.3% of Australia. In contrast, Ecological Fire Regimes and Invasive Rabbit management have 479 lower associated management costs (mode of \$1,464/km² and \$1,426/km²) but are projected 480 over a large extent of Australia (100% and 82%) (Fig. 4). The exception was Invasive Weed 481 Management that had a moderate to high cost per km² (mode of \$24.5k/km²) but was required 482 across a broad range of Australia (64%).

483

Travel costs were generally higher in the central-west of Australia, and for strategies with the
lower labour, consumable and equipment costs, the travel cost in these regions represented a

- 186 larger proportion of overall costs (TASs on the left half of Fig. 4). For TASs with action costs
- that had low spatial variation the travel to site costs represented the source of overall cost
- variation. For example, for Disease management and Invasive Rabbit management, expensive
- pockets occur in remote areas due to travel to site and viral consumable costs increasing by up
- 490 to ~2 fold (Supp. Material 12). For higher cost/km² TASs, the travel to site costs were not as
 - ⁴⁹¹ visible due to the lower contributing proportions. For example, Invasive Weed Management had
 - a labour-intensive weeding action cost that out shadowed the "remoteness" travel to site cost,
 - with the spatial variation instead driven mostly by intactness and aridity (Supp. Material 12).

- Figure 4. The spatial cost layers for 16 spatially variable Threat Abatement Strategies that include the travel time to site (inset
- 496 ground travel time and air travel distance). These were projected to the threat range, and Australia-wide if there was no determined
- 497 threat range.

498 **Discussion**

499 We provide a novel threat abatement budgeting tool for estimating the costs of a comprehensive set of generic threat management strategies impacting 500 501 biodiversity across Australia. The cost estimates and approaches for applying 502 them are transparent and updatable, allowing for continual improvements in 503 conservation planning that is better informed by knowledge of threat 504 management costs. Our approach builds on existing information focussed on 505 the actions and resources required to abate threats to biodiversity (Brazill-506 Boast et al. 2018; DPIE 2021; Ward et al. 2021) and costing out threat 507 abatement efforts at smaller spatial scales (Cattarino et al. 2018; Wenger et 508 al. 2018; Carwardine et al. 2019; Thomson et al. 2020). The three outputs 509 provided can help plan for on-ground management and inform decision-510 making across broader scales. First, a set of expert-derived assumptions that 511 define the 18 TASs. Secondly, a mechanistic cost model for each strategy 512 that can be applied or modified to suit the locally determined locations and 513 extent of management. Third, spatially variable TAS cost maps that can 514 estimate management effort across large scales.

515

516 Our models show that the cost of managing a threat to biodiversity across 517 Australia are likely to vary from \$24 - \$1.02m /km², depending on the TAS 518 required, the travel distance to site and the site characteristics. Our per km² 519 cost estimates were similar or higher than cost estimates from previous 520 analyses, which is likely due to the comprehensive inclusion of all cost 521 components in our cost models, including planning, travel to site and labour 522 on-costs (see Supp. Material 7).

523

524 Improving the use of consistent standardised financial reporting is important 525 for the effectiveness of the conservation sector (Cook *et al.* 2017; Iacona *et al.* 2018). Current conservation investments largely occur without reliable 526 information on the costs of how the investment will be spent, and 528 conservation expenditure is typically not recorded in ways that can improve

- 529 current knowledge of conservation costs. The bottom-up costing model
- 530 structure we provide can inform, and be improved by, the collection of
- additional cost information. By consistently recording the costs of
- 532 individualised components of threat abatement activities, it becomes possible
- 533 to understand the make-up of a total strategy cost and leverage these
- 534 estimate costs elsewhere.
- 535

536 The collection of improved data on conservation expenditure should be used 537 to improve the accuracy and precision in the presented cost models. Our 538 uncertainty analysis indicated our estimates had a range of (-34%, +55%) for 539 the baseline TAS values, and this variation needs to be accounted for when 540 applying the cost estimates. We modified only global parameters, and further 541 investigation of action specific parameters could reveal other parameters 542 influencing cost estimates. A value of information (VoI) analysis approach 543 estimates the higher expected payoff from better decision making as a result 544 of reducing uncertainty (Raiffa & Schlaifer 1961), and Vol analyses are only 545 just gaining traction in the realm of conservation decision making (Bolam et 546 al. 2019). A Vol analysis can help prioritise the collection of improved 547 information for the parameters which influence the cost estimates and 548 subsequent management investment decisions.

549 Conclusion

550 Every year billions of dollars are spent on conservation management 551 worldwide (Waldron et al. 2013). This expenditure largely occurs without a 552 priori estimates of conservation management costs across broad scales and 553 is not recorded in ways that can inform future conservation management 554 budgets and analyses comparing the relative cost-effectiveness of actions. 555 Our work provides new guidance on consistent approaches for estimating, 556 recording, and informing cost estimates that can be built on or adapted with 557 additional information from local to national scales. We aim to enable the 558 conservation industry to match other sectors in articulating the investment 559 required to achieve its sought goals. By continuing to progress knowledge on

- 560 the costs of managing threats to biodiversity, more strategic revenue raising
- and improved use of available resources to achieve conservation outcomes
- 562 are possible.

563 Author Contributions

- 564 CY, JW, MW, AR, JC conceived the ideas and design methodology; CY
- 565 collected the data with contribution and direction from SvL, SL, WG, SS, ML,
- and MK. CY and MW analysed the data; CY, JW and JC led the writing of the
- 567 manuscript. All authors contributed critically to the drafts and gave final
- 568 approval for publication.

569 Acknowledgements

- 570 The cost estimates and modelling approach were co-developed through
- 571 expert input during two online workshops and follow-up discussions in 2020-
- 572 2021, involving the co-authors and additional participants (see Supp. Material
- 573 13).
