30 **Abstract**

31 Biodiversity metrics are increasingly in demand for informing government,  
32 businesses, and civil society decisions. However, while there are many metrics  
33 available, it is not always clear to end-users how they differ or for what purpose they  
34 are best suited. This confusion undermines uptake. Here, we seek to clarify these  
35 questions by reviewing and presenting a database of 573 biodiversity-related  
36 metrics, indicators, indices and layers (hereafter 'metrics'). Of these metrics, 227 are  
37 spatial data layers and 272 are temporal indicators. Assessed in relation to the  
38 pressure-state-response-benefits framework, 213 address only state, 118 address  
39 only pressures, 124 address only responses and 8 address only benefits. The  
40 remaining 110 relate to combinations of the four. Among the state indicators, 217 are  
41 bottom-up metrics (aggregated from individual components), 57 top-down (compiled  
42 through extrapolation), 8 are neither, and 1 is both; while 61 measure significance  
43 ('biodiversity importance') 86 intactness ('biodiversity condition'), 5 both, and 131 are  
44 neither. These metrics address aspects of genetic diversity (19), species (106) and  
45 ecosystems (214), with 38 covering more than one aspect and 196 being general  
46 metrics. Considering complementarity across these characteristics, we recommend a  
47 small number of metrics considered most pertinent for use in decision-making by  
48 governments and businesses. We conclude by highlighting five future directions:  
49 increasing the importance of national metrics, ensuring wider uptake of business  
50 metrics, agreeing a minimum set of metrics for government and business use,  
51 automation of metric calculation through use of technology, and generating  
52 sustainable funding for metric production.

80			

## 81 1 Introduction

82 In recent years, governments, civil society, and business have made a series of  
83 pledges and commitments to address the dual climate and biodiversity crises. These  
84 have been seen at the 15<sup>th</sup> meeting of the Conference of the Parties (COP15) to the  
85 [Convention on Biological Diversity](#) (CBD), the UN Framework Convention on Climate  
86 Change (UNFCCC), the 2030 Agenda for Sustainable Development and its  
87 Sustainable Development Goals (SDGs), as well as at private sector-facing events  
88 like the World Economic Forum (WEF).

89 At CBD COP15, Parties to the CBD adopted a package of decisions related to the  
90 Kunming-Montreal Global Biodiversity Framework (GBF), which contains 4 [goals](#), 23  
91 [targets](#) and an associated monitoring framework comprising a suite of headline  
92 indicators, component and complementary indicators (Box 1). The GBF  
93 complements mechanisms under the other biodiversity-related conventions and adds  
94 specificity to SDG 14 (life below water) and SDG 15 (life on land) and their  
95 associated 24 indicators. Together, these form the political basis for international  
96 action to conserve biodiversity and its contributions to people, driving progress  
97 towards implementation of actions by 2030 and achievement of goals by 2050 (1).

98 The GBF goals focus on outcomes (e.g. the state of biodiversity) while the targets  
99 focus on actions (e.g. to reduce the threats to biodiversity, how it can be sustainably  
100 used to provide equitable benefits for people, and how to ensure that there is  
101 sufficient finance and capacity to deliver the adopted decisions) (1). To guide  
102 implementation and measure progress towards the goals and targets, robust  
103 biodiversity metrics are required for the [monitoring framework](#) of the GBF (2), and the  
104 SDG indicators framework (3), with both aiming to measure progress towards global  
105 sustainability aspirations.

106

### 107 **Box 1: The Kunming-Montreal Global Biodiversity Framework and** 108 **associated package of decisions**

109 The Kunming-Montreal Global Biodiversity Framework (GBF) (Decision 15/4) was  
110 adopted during the fifteenth meeting of the Conference of the Parties ([COP 15](#)). This  
111 historic Framework builds on previous strategic plans under the CBD, and sets out

112 an pathway to reach the global vision of a world living in harmony with nature by  
113 2050.

114 The implementation of the GBF is supported through a package of decisions  
115 adopted alongside the GBF, at CBD COP15. The package includes a monitoring  
116 framework (Decision 15/5), an enhanced multidimensional approach for planning,  
117 monitoring, reporting and review of implementation of the GBF (Decision 15/6), a  
118 series of decisions relating to the means of implementation that will be necessary to  
119 enable an effective implementation of the framework (resource mobilization –  
120 Decision 15/7-, capacity building and development and technical and scientific  
121 cooperation –Decision 15/8), and finally, an agreement regarding the fair and  
122 equitable sharing of benefits from the use of digital sequence information on genetic  
123 resources (Decision 15/9).

124 Parties to the CBD committed to implementation of the GBF and related decisions  
125 through aligned national targets in their revised national biodiversity strategies and  
126 action plans (NSBAPs). A global analysis of national targets submitted by the next  
127 meeting of the Conference of the Parties (CBD COP16) will be made available for  
128 discussion. Later on, at CBD COP17, a global review of collective progress in  
129 implementation of the Framework will be discussed. In this context, the monitoring of  
130 implementation by governments, and other stakeholders will be essential to  
131 understand the progress that has been made towards the 2030 targets. Robust  
132 metrics, used by Parties and non-state actors will be key input to the global review of  
133 collective progress.

134

135 Furthermore, the need for business and financial institutions to measure their  
136 impacts and dependencies on biodiversity continues to grow in response to investor,  
137 regulatory and societal pressure (4, 5). Increasing numbers of businesses are calling  
138 for greater ambition from governments and have made commitments to implement  
139 the agreements made at climate and biodiversity COPs, with over 5,800 businesses  
140 setting climate targets aligned to the [Paris Climate Agreement](#) and over [1,400 calling  
141 for action on biodiversity](#) at CBD COP15. Several voluntary and mandatory  
142 frameworks and standards are emerging to support nature-related assessments,  
143 disclosures and target-setting by businesses. Examples of voluntary frameworks and

144 standards include the [Taskforce on Nature-related Financial Disclosures \(TNFD\)](#)  
145 (focused on nature in general), the [Science Based Targets Network](#) (focused on  
146 freshwater and land), the [IUCN Nature Positive Initiative](#) (focused on biodiversity) and  
147 the [Global Reporting Initiative](#) (GRI) Standards (focused on sustainability including  
148 dedicated standards for selected environmental issues).

149 Mandatory regulatory requirements, which apply to business and the trade system  
150 between governments, are also emerging. These can be seen, for example, in the  
151 European Union (EU) [Due Diligence](#) Directive, [Deforestation Regulation](#), [Corporate](#)  
152 [Sustainability Reporting Directive](#), and [France's Article 29](#). The International Finance  
153 Corporation's [Performance Standard 6 on Biodiversity](#), widely adopted by the  
154 regional development banks and the Equator Principles financial institutions, adds  
155 momentum by making access to capital dependent on biodiversity metrics and  
156 reporting. The [International Sustainability Standards Board](#) (ISSB) general  
157 sustainability disclosure and climate disclosure standards are expected to be  
158 mandated in jurisdictions across the globe over time. The International Standards  
159 Organisation (ISO) has now established a [Technical Committee 331 on Biodiversity](#).

160 As political and business commitments have been established, and scientists have  
161 increasingly engaged in these processes, numerous metrics (systems or standards  
162 of measurement) for biodiversity have been proposed and conceptualised. Many of  
163 these have been developed into readily available tools and data layers for  
164 application by users. This proliferation of metrics (and tools delivering them) makes it  
165 difficult for end users to know are the most reliable, scientifically robust and  
166 appropriate for different use cases (6). This problem is exacerbated by the  
167 complexity of many metrics, and the inaccessibility of their methodologies and/or  
168 underlying data.

169 In this review, we present an assessment of available biodiversity metrics, indicators,  
170 indices (collectively termed "metrics" from now on), which have been developed for  
171 use in decision-making by governments, businesses, financial institutions and civil  
172 society (Annex 1). We distinguish these metrics from the scientific discussion on the  
173 different ways of quantifying biodiversity change (e.g., 7).

174 All metrics were reviewed against the causal-chain State, Pressure, Response and  
175 Benefit (SPRB) framework, widely used for identification and reporting against  
176 indicators (8–10) (Box 2; Figure 1).

### 177 **Box 2: State, Pressure, Response and Benefit (SPRB) framework**

178 The SPRB framework was adapted from the Organisation for Economic Co-  
179 operation and Development (OECD) "[Pressure-State-Response](#)" model (11, 12), and  
180 was adopted by the CBD to guide indicator development (13). This framework links  
181 changes in the **state** or condition of biodiversity (e.g., habitat extent, species'  
182 extinction risk), with the **pressures** resulting from human activities (e.g., agriculture,  
183 pollution, invasive alien species, species utilisation). Society then **responds** to these  
184 by implementing environmental and economic policies or actions, intended to reduce  
185 or mitigate the pressures, and this recover the state of the natural resource. These  
186 responses should in turn improve the **benefits** that humans derive from the  
187 environment (e.g., pollination, air quality, scenic beauty), also known as "ecosystem  
188 services" or "nature's contributions to people". The inclusion of this fourth category is  
189 important in the context of biodiversity policy and practice and justifies our use of the  
190 SPRB framework rather considering only State-Pressure-Response. However, we  
191 did not use the expanded "drivers, pressures, state, impact and response" (DPSIR)  
192 model as drivers and pressures are hard to separate Among metrics of the state of  
193 biodiversity, we also classify those derived from bottom-up relative to top-down  
194 approaches, and those measuring significance relative to those measuring  
195 intactness (14).

196

### 197 **Box 3: Definition of key terms**

198 **Data:** The structured information used to create metrics, indicators and indices.

199 **Metric:** A system or standard of measurement. For example, biodiversity  
200 observations, collected over space and/or time can be used to form a metric that tells  
201 us something about biodiversity – either directly (e.g. number of species observed),  
202 or indirectly (e.g. habitat extent). **In the context of this paper, we use "metric" to**  
203 **include indicators, indices and spatial data that provide information on**  
204 **pressure, state, responses or benefits.**

205 **Indicators:** Indicators are measures that are based on verifiable data that convey  
206 information beyond their own context. An **indicator** requires an external context, as  
207 they are purpose-dependent and so their interpretation depends on the issue being  
208 examined. To become an indicator, a **metric** must either a) be presented in the  
209 context of progress towards a target (e.g. the metric shows progress towards a  
210 target to increase forest extent by x%), or b) be used to assess the effectiveness of  
211 an intervention (e.g. changes in forest cover inside protected areas can be used to  
212 indicate the effectiveness of protected areas at maintaining or delivering greater  
213 forest extent).

214 **Index:** A numerical scale used to compare variables with one another or with some  
215 reference number. An index can be made from an aggregation of data, metrics or  
216 indicators (although aggregating data is recommended). Indices aim to reduce  
217 complexity into individual measure(s).

218 **Platforms:** These are systems, typically available online, that bring information to  
219 users. They may (or may not) have an associated metric. For the purposes of this  
220 review, we have focused on platforms with a biodiversity metric included. A sample  
221 of biodiversity-related platforms are listed in Annex 2.

222 For **State, Pressure, Response and Benefits** the following definitions are relevant:

223 **Biodiversity state metrics** quantify the condition of biodiversity (e.g., habitat extent,  
224 species extinction risk, ecosystem condition, genetic diversity).

225 **Biodiversity pressure metrics** quantify how and where biodiversity state is being  
226 impacted by pressures (e.g., agriculture, pollution, invasive alien species, species  
227 utilisation)

228 **Biodiversity response metrics** quantify policies or management actions that aim to  
229 reduce or mitigate the pressures or otherwise help recover the state of nature (e.g.  
230 establishment and management of protected areas, biosecurity, eradication, and  
231 management of invasive alien species, restoration interventions).

232 **Biodiversity benefits metrics** quantify what people derive from biodiversity (e.g.,  
233 pollination for human crops, air quality for human health, scenic beauty for human  
234 enjoyment), otherwise known as ecosystem services.

235 Complementing these definitions, recent work has also introduced additional  
236 dimensionality to the classification of biodiversity metrics (14):

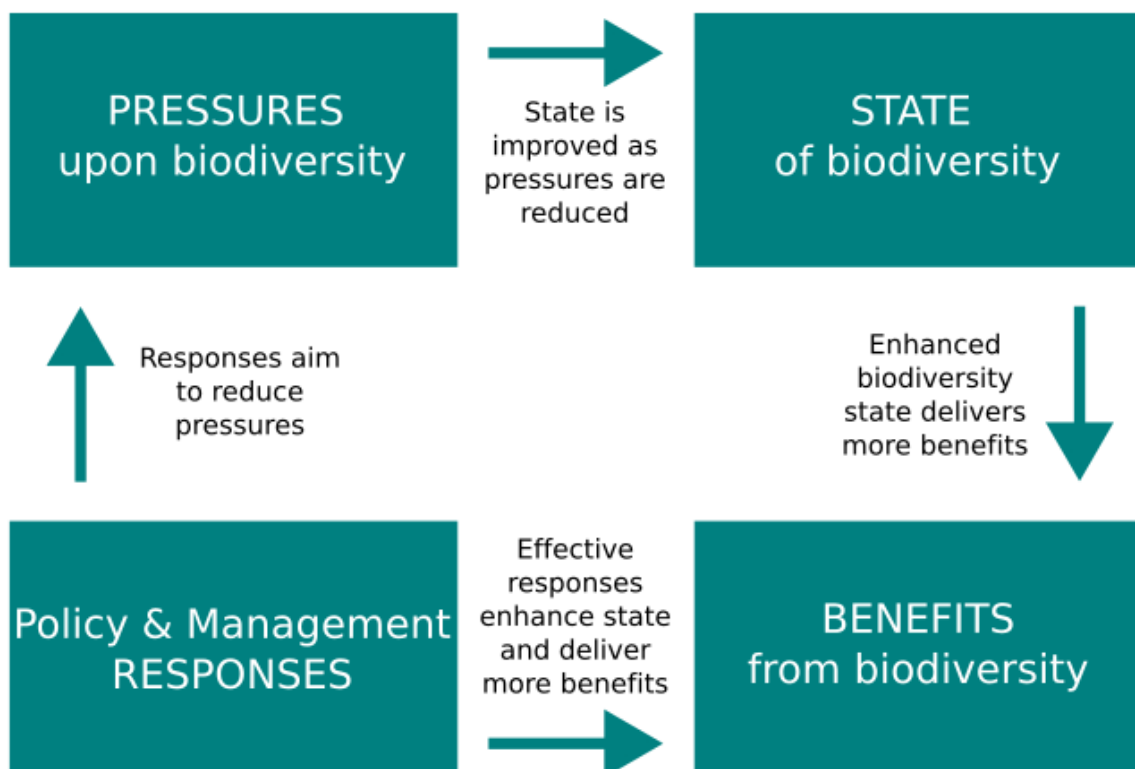

237 **Bottom-up** metrics are based on features measured at the level of an individual  
238 component of biodiversity (e.g. species within a class) and then aggregated.

239 **Top-down** metrics are measured by extrapolating or modelling biodiversity features  
240 from samples across a given ecological unit (ecosystem, habitat). Often the  
241 modelling includes the impacts caused by threats.

242 **Intactness** metrics measure biodiversity in a given place and time with respect to  
243 some pre-determined historical or spatial baseline (e.g. 1970, pre-human, when  
244 remote sensing data became available).

245 **Significance** metrics compare the relative importance of losses or gains in  
246 biodiversity across space and time.

247

248

249 **Figure 1.** Graphical representation of the State-Pressure-Response-Benefits model  
250 often used in biodiversity measurement. Figure adapted with permission from Sparks  
251 et al. (8).

252 For this paper, we adopt the Convention on Biological Diversity (CBD) [definition of](#)  
253 [biodiversity](#), which encompasses three different components: genetic diversity,  
254 species and ecosystems (Box 4). These components each contain a variety of  
255 different features that each requires different metrics to measure. For an overview of  
256 how biodiversity is defined across disciplines, as well as a review of the values,  
257 patterns and trends of biodiversity, see Díaz and Malhi (15).

258

#### 259 **Box 4: The three components of biodiversity and example features**

260 According to the CBD: "[Biological diversity](#)" means the variability among living  
261 [organisms from all sources including, inter alia, terrestrial, marine and other aquatic](#)  
262 [ecosystems and the ecological complexes of which they are part; this includes](#)  
263 [diversity within species, between species and of ecosystems.](#)"

264

265 Components	Example features
266 Genes	267 Within species diversity, between species diversity (phylogenetic diversity)
268 Species 269 distribution	268 Extinction risk, Population abundance, changes in
270 Ecosystems	269 Extent, condition, risk of collapse

271

272 We focus this review on terrestrial biodiversity metrics. This is partly because there  
273 are smaller bodies of work on metrics for freshwater (16–20) and for marine (10, 21–  
274 23). Nevertheless, many of the metrics we review do have application in these other  
275 biomes, sometimes with adjustments to the specific conditions in freshwater and  
276 marine systems.

277

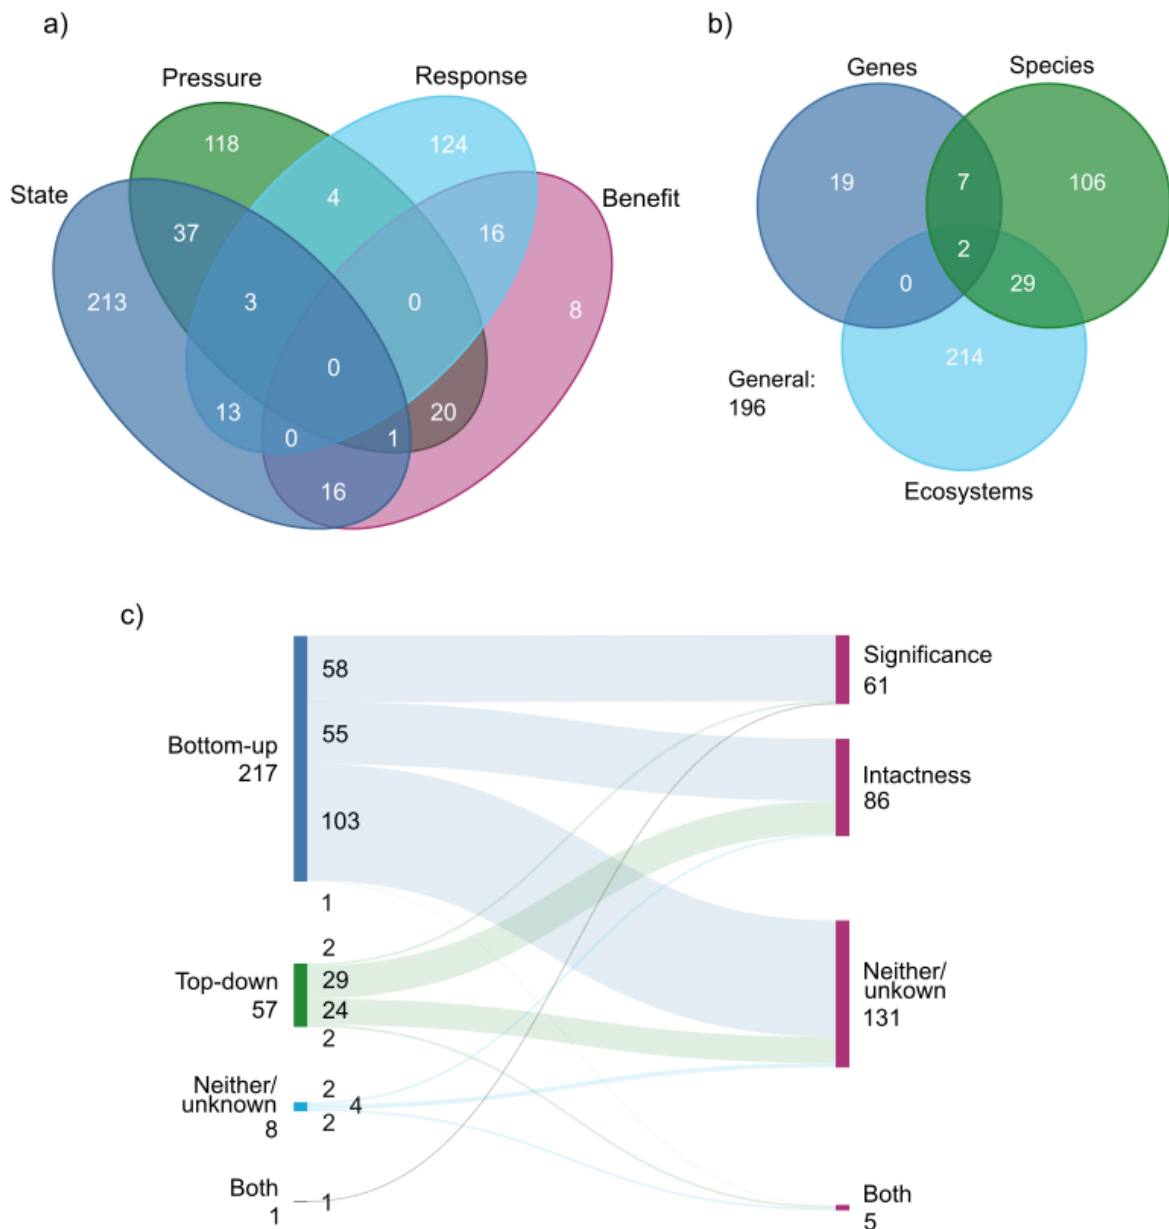

## 278 **2 Reviewing the Metrics**

279 We compiled a database of biodiversity metrics (covering indicators, indices and  
280 relevant data layers: Annex 1). No formal literature search protocol was used.

281 Instead, we built our database from several existing lists. These included lists  
282 compiled of possible indicators to support the development of the monitoring  
283 framework for the GBF (24–27) based on information provided by the [Biodiversity](#)  
284 [Indicators Partnership](#), an inventory of spatial datasets developed to support  
285 governments and business with spatial planning for biodiversity (28), an assessment  
286 of the role of remote sensing in spatial planning for biodiversity (29), and a review of  
287 top-down intactness compared to bottom-up significance metrics (14). These existing  
288 lists were first combined and standardised. We then added new metrics from an  
289 assessment of papers published in 2023 and early 2024. We removed platforms and  
290 databases that provide biodiversity data but lack an associated biodiversity metric  
291 (See Annex 2).

292 Each metric was assessed by NB and MH in terms of their relevance to spatial or  
293 temporal aspects of biodiversity state, pressure, response or benefits (Figure 1), and  
294 the biodiversity elements of genes, species or ecosystems (see Box 3). These  
295 comparisons yielded greater than 70% agreement, with the remainder harmonised  
296 through discussion. Each metric was further assessed in the current and potential  
297 use of the metric for the GBF, SDGs, and by businesses. Similarly, for biodiversity  
298 state metrics, the classifications of bottom-up/top-down and significance/intactness  
299 were assessed by FH and TB, yielding 96% agreement, and mismatches were  
300 harmonised through discussion.

301 In the process of our review, it became clear that some metrics that are most  
302 appropriately classified as state metrics (e.g., extinction risk of species) also provide  
303 information on measurement of pressures. We found that some also contain  
304 information relevant to responses. Others that were assessed as measuring benefits  
305 to people also created pressures on biodiversity where the use was unsustainable.  
306 These non-mutually exclusive classifications are documented in Annex 1. Through  
307 our review process, we identified 573 metrics that aim to measure different elements  
308 and features of biodiversity (Annex 1), within the frameworks of State-Pressure-  
309 Response-Benefits (Figure 2a; Table S1), genes-species-ecosystems (Figure 2b;  
310 Table S2), and top-down/bottom-up and significance/intactness (Figure 2c; Table  
311 S3).

312

313 **Figure 2.** Overview of the 573 metrics reviewed and presented in Annex 1. (a)  
 314 Number and overlap between metrics classified within the State-Pressure-  
 315 Response-Benefit framework; (b) Number and overlap between metrics classified  
 316 within the Genes-Species-Ecosystems framework; (c) Top-down/Bottom-up &  
 317 Intactness/significance. Diagram created using SankeyMATIC. For tabular data see  
 318 Tables S1-S3.

319

320

321

### 322 **3 Aligning metrics to users**

323 Biodiversity metrics are required by different user communities. The main user  
324 groups of these metrics are governments (including policy makers and public  
325 bodies/authorities at national, subnational and even city levels), business and trade-  
326 related bodies (corporations with supply chains, financial institutions, credit ratings  
327 agencies, trade organisations and intergovernmental trade agreements), technical  
328 agencies (international organisations, NGOs, universities), and civil society  
329 encompassing local communities and citizens (indigenous people, general public,  
330 resource users). We use information in Annex 1 to highlight metrics, indicators and  
331 indices proposed for use by governments (Table 1) and provide examples of how  
332 they are being used.

	State	Pressure	Response	Benefit	All
<b>GBF</b>	56	41	81	22	155
Headline	4	0	9	2	14
Component	16	13	11	4	32
Complementary	47	32	64	17	124
<b>SDG</b>	13	12	43	9	66

333

334 **Table 1:** Numbers of metrics agreed for use under the GBF and SDGs that were  
335 included within our analysis. The sum of headline, component and complementary  
336 indicators does not add up to the total GBF indicators as some indicators are classed  
337 as more than one if they are under different targets.

338

#### 339 **3.1 Governments**

340 Biodiversity metrics for use by governments in relation to international and national  
341 policies and laws may be politically agreed at various scales (global, regional,  
342 national and sub-national). For example, the Parties to the CBD adopted a set of 26  
343 headline indicators to track progress towards the goals and targets of the GBF, along  
344 with a further 58 component and 230 complementary indicators that governments  
345 can use subject to national needs (30). Similarly, 24 biodiversity-related indicators

346 have been adopted by the world's governments to track progress towards the  
347 Sustainable Development Goal 15. These metrics are highlighted in Annex 1. We  
348 provide a shortened list of options for government and civil society use (Table S4,  
349 S6) and indicate online sources for these metrics, with other online platforms listed in  
350 Annex 2.

351

### 352 **3.2 Business and trade-related bodies**

353 There is a growing recognition that biodiversity is associated with significant financial  
354 risks and opportunities for businesses (4, 5). There are also emerging regulatory  
355 requirements for businesses to report on their climate- and nature-related risks (31).  
356 Target 15 of the GBF, and to some extent Target 16, provide a political impetus for  
357 CBD Parties to encourage businesses to assess biodiversity risks, disclose those  
358 risks, dependencies and impacts on biodiversity and develop targets to reduce  
359 negative impacts (1).

360 Various initiatives provide or are developing guidance on biodiversity metrics for  
361 corporations and finance bodies across value chains, for example, through the  
362 [TNFD](#), [GRI](#), [SBTN](#), [EU Business@Biodiversity Platform](#), the [Align](#) project, [Natural](#)  
363 [Capital Protocol](#), the [IUCN Measuring Nature Positive approach](#), and the World  
364 Economic Forum (WEF) '[measuring stakeholder capitalism](#)' initiative. An emerging  
365 trend across these initiatives is a growing recognition that businesses need to  
366 contextualise the pressures that they place on nature using information on the state  
367 of nature, which should be measured by assessing the extent and condition of  
368 ecosystems, alongside population size and extinction risk of species (e.g., 14, 31).

369 Corporate biodiversity 'footprinting' tools often rely on the use of modelled pressure-  
370 state relationships (i.e., top-down intactness metrics) to estimate impacts across the  
371 business value chains. For example, the tools Global Biodiversity Score (32),  
372 Corporate Biodiversity Footprint (33) and the Biodiversity Impact Metric (34) use the  
373 Mean Species Abundance (MSA) metric. The latter, weights MSA by species range  
374 rarity derived from the IUCN Red List (35). The widely used life cycle impact  
375 assessment (LCIA) method [ReCiPe](#) (36) applies the potentially disappeared fraction  
376 of species (PDF) metric (37) for biodiversity impact assessment. The ReCiPe  
377 method is further utilised in business-oriented Life Cycle Assessment (LCA)

378 approaches such as the Biodiversity Footprint for Financial Institutions (38) and  
379 Bioscope (39). These approaches need to be complemented with bottom-up  
380 significance metrics such as STAR (40, Box 3), not least to ensure their alignment  
381 with and track their contributions towards global goals such as the GBF and SDG 15.  
382 A shortened list of options of metrics for business use is presented online (Table S5)  
383 which also indicates online sources.

384 Whilst global metrics are most applicable for screening processes, metrics based on  
385 primary data are often needed to calculate actual, realised footprints on the ground  
386 and track outcomes of management decision making, for example in Environmental  
387 Impact Assessment processes. These metrics tend to be precise for local  
388 application, but can be challenging to apply at scale as different metrics tend to be  
389 used for different locations and activities, creating challenges of aggregation for  
390 reporting and disclosure (41). Methods to assess site scale impacts have been  
391 developed for [development corridors and linear infrastructure](#), extractives (42),  
392 agriculture (43) and forestry (44, 45), for example.

393

## 394 **4 Detailed Review of Metrics**

### 395 **4.1 Biodiversity State**

396 Biodiversity state metrics describe the status and changes in status of components  
397 of biodiversity (genes, species and ecosystems). State measures are critical for  
398 understanding the health of the biosphere and the balance between the negative  
399 impacts of pressures and positive impacts of responses. However, measuring  
400 changes in the state of biodiversity does not necessarily reveal *why* it is changing.  
401 Therefore, it is crucial to explore the links between state metrics and those for  
402 pressures and responses to inform decision-making.

#### 403 **4.1.1 Genes**

404 The CBD definition of this component of biodiversity covers the ‘within species’  
405 aspect of genetic diversity (Box 4). Intraspecific genetic variability is critical not only  
406 intrinsically, but also to ensure species are resilient to environmental change (46).  
407 The importance of genetic diversity and sharing its benefits is also recognised under  
408 Target 13 of the GBF.

409 Despite its importance, few datasets are available to assess the within-species  
410 genetic element. Metrics of genetic diversity within wild mammal and amphibian  
411 species (47) complement work on metrics of genetic diversity within domesticated  
412 species by the Food and Agriculture Organisation of the United Nations (48). In the  
413 GBF Monitoring framework, the proportion of populations within each species with an  
414 effective population size of more than 500 individuals has been adopted as headline  
415 indicator A4. It acts as a proxy for loss of genetic diversity but is recognised as  
416 insufficient (49). Hoban et al. (50) also proposes a further metric of “the proportion of  
417 populations maintained within species,” which reflects the loss of genetic  
418 distinctiveness of each population. Most of the above are bottom-up metrics of  
419 biodiversity intactness. Significance metrics have yet to be developed for genetic  
420 biodiversity.

421 The ‘between species’ element of genetic diversity (see Box 2) can be assessed  
422 using phylogenetic diversity metrics, which are bottom-up metrics of biodiversity  
423 significance. These measure the shared ancestry of taxonomic groups and the  
424 breadth of evolutionary history. They represent the evolutionary distance between

425 coexisting taxa (51). A number of phylogenetic diversity metrics are available for  
426 vertebrate groups (52–55) and flowering plants (56) on land and can be used to  
427 identify (and maintain) areas of greater genetic diversity in terms of distance  
428 between taxa (i.e. maintaining the results of evolutionary history). However, work to  
429 date suggests that these do not add substantial information content over and above  
430 that provided by species-level significance metrics (55).

#### 431 **4.1.2 Species**

432 Many metrics of the state of species use either data on birds, mammals, amphibians  
433 and reptiles, largely due to a shared reliance on International Union for the  
434 Conservation of Nature (IUCN) Red List of Threatened Species (16, 35) or data on  
435 selected vascular plant groups (57–61). Vertebrates and vascular plants are  
436 therefore often used as surrogates for wider biodiversity (e.g., 62) applications which  
437 have been shown to be rather robust (63), despite the fact that plants, invertebrates  
438 and fungi sometimes differ in their distribution patterns (e.g., 64). The IUCN Red List  
439 contains information on species distributions, population size, structure and trends,  
440 habitat preferences, threats and actions needed and implemented for over 150,000  
441 species (35). These data are applied to a set of criteria (65) to classify species' risk  
442 of extinction, with 42,100 classified as threatened with extinction.

443 Measurements of species extinction risk from the IUCN Red List can then be  
444 aggregated to yield bottom-up metrics of biodiversity significance, such as STAR  
445 (40) and LIFE (66). STAR specifically, for example, is a wholly scalable and additive  
446 measure of global specific risk reduction opportunity. Further, repeated assessments  
447 of species' extinction risk over time enable calculation of the Red List Index (9, 67)  
448 for complete suites or random samples of species, showing how their aggregate  
449 extinction risk has changed over time. This is adopted as GBF headline indicator A3  
450 and SDG indicator 15.5.1. These are all bottom-up metrics of biodiversity  
451 significance. Meanwhile, the IUCN green status of species (68, 69) aims to measure  
452 different dimensions of species recovery. It is meant to be used in tandem with the  
453 assessment of extinction risk.

454 Metrics relating to distribution and diversity are also becoming available to cover  
455 biodiversity patterns of non-vascular plants or invertebrates, e.g. for soil biota such  
456 as fungi (70), earthworms (71) and soil nematodes (72). Nevertheless, the lack of

457 data on some of the most speciose groups (71, 73–75) means that for the  
458 foreseeable future, species level biodiversity metrics will need to be based on  
459 surrogacy and samples of all species on Earth. This has been known for decades  
460 and is only slowly being addressed.

461 The Global Biodiversity Information Facility (GBIF, <https://www.gbif.org/>) brings  
462 together 2.38 billion (as of 9 October 2023) occurrence records from museums,  
463 herbaria, citizen scientists, and environmental impact assessments. The main metric  
464 generated using GBIF is the number of records available for use, as a proxy for  
465 availability of biodiversity data, but GBIF data are fed into many other metrics on  
466 biodiversity state, including the IUCN Red List assessment process.

467 Species range data from the IUCN Red List and point locality data from GBIF and  
468 other sources are often paired with land cover and topography, and sometimes  
469 distance to water and other factors, to model species' distributions and changes in  
470 these resulting from loss or gain of habitat. Range polygons (showing distributional  
471 boundaries) can be refined using data on species' elevation and habitat preferences  
472 in combination with land-cover maps to estimate bottom-up metrics of Area of  
473 Habitat (AOH) (76, 77). With its higher spatial resolution, AOH is more useful for  
474 spatial analyses of biodiversity values than the underlying range maps (see 77, 78)  
475 and is used to underpin STAR, LIFE, and other metrics (examples in Figure 4).

476 The [Living Planet Database](#) brings together more than 38,427 geolocated species  
477 population datasets (61) and is used to generate the Living Planet Index (LPI). The  
478 LPI is a measure of the state of population trends of vertebrate species, as a bottom-  
479 up intactness metric.

480 There are different aspects of connectivity including structural and functional  
481 connectivity. Areas where the flow of species movement is concentrated are places  
482 with the potential to disproportionately reduce connectivity (79) (Brennan et al. 2022).  
483 The Protected Area Isolation (PAI) is a metric that quantifies the connectedness of  
484 each protected area through the lens of moving mammals, using mammal movement  
485 data.

### 486 **4.1.3 Ecosystems**

487 More than 100 years' work to classify ecosystems underpins the creation of  
488 ecosystem metrics reflecting area and condition, with the most recent advance in

489 ecosystem classification being the development of the IUCN Global Ecosystem  
490 Typology (80, 81).

491 The most common metrics of ecosystem state are those linked to land cover and  
492 land use maps, especially those that measure changes over time, incorporated into  
493 the GBF as headline indicator A2 on the extent of natural ecosystems. Bottom-up  
494 intactness metrics that assess individual ecosystems extent across the world are  
495 increasingly available – such as forests (82–84), mangroves (85), seagrass (86),  
496 saltmarsh (87), coral reefs (88), peatlands (89), wetlands and water bodies (90, 91).  
497 Challenges remain to measure the extent of some ecosystems – for example, in  
498 differentiating natural grasslands from pasture or croplands, differentiating natural  
499 forest from plantations or tree crops (e.g., rubber, palm oil, 92), distinguishing  
500 peatland ecosystems from similar vegetation and identifying mixed-use land – such  
501 as mosaic habitats or shade-grown crops. At finer scales, the gradual emergence of  
502 standardisation in land use and land cover classifications, and the creation of  
503 national land cover and land use maps for most countries, facilitates using satellite  
504 remote sensing data to measure changes in ecosystem area and condition at local to  
505 national scales (29).

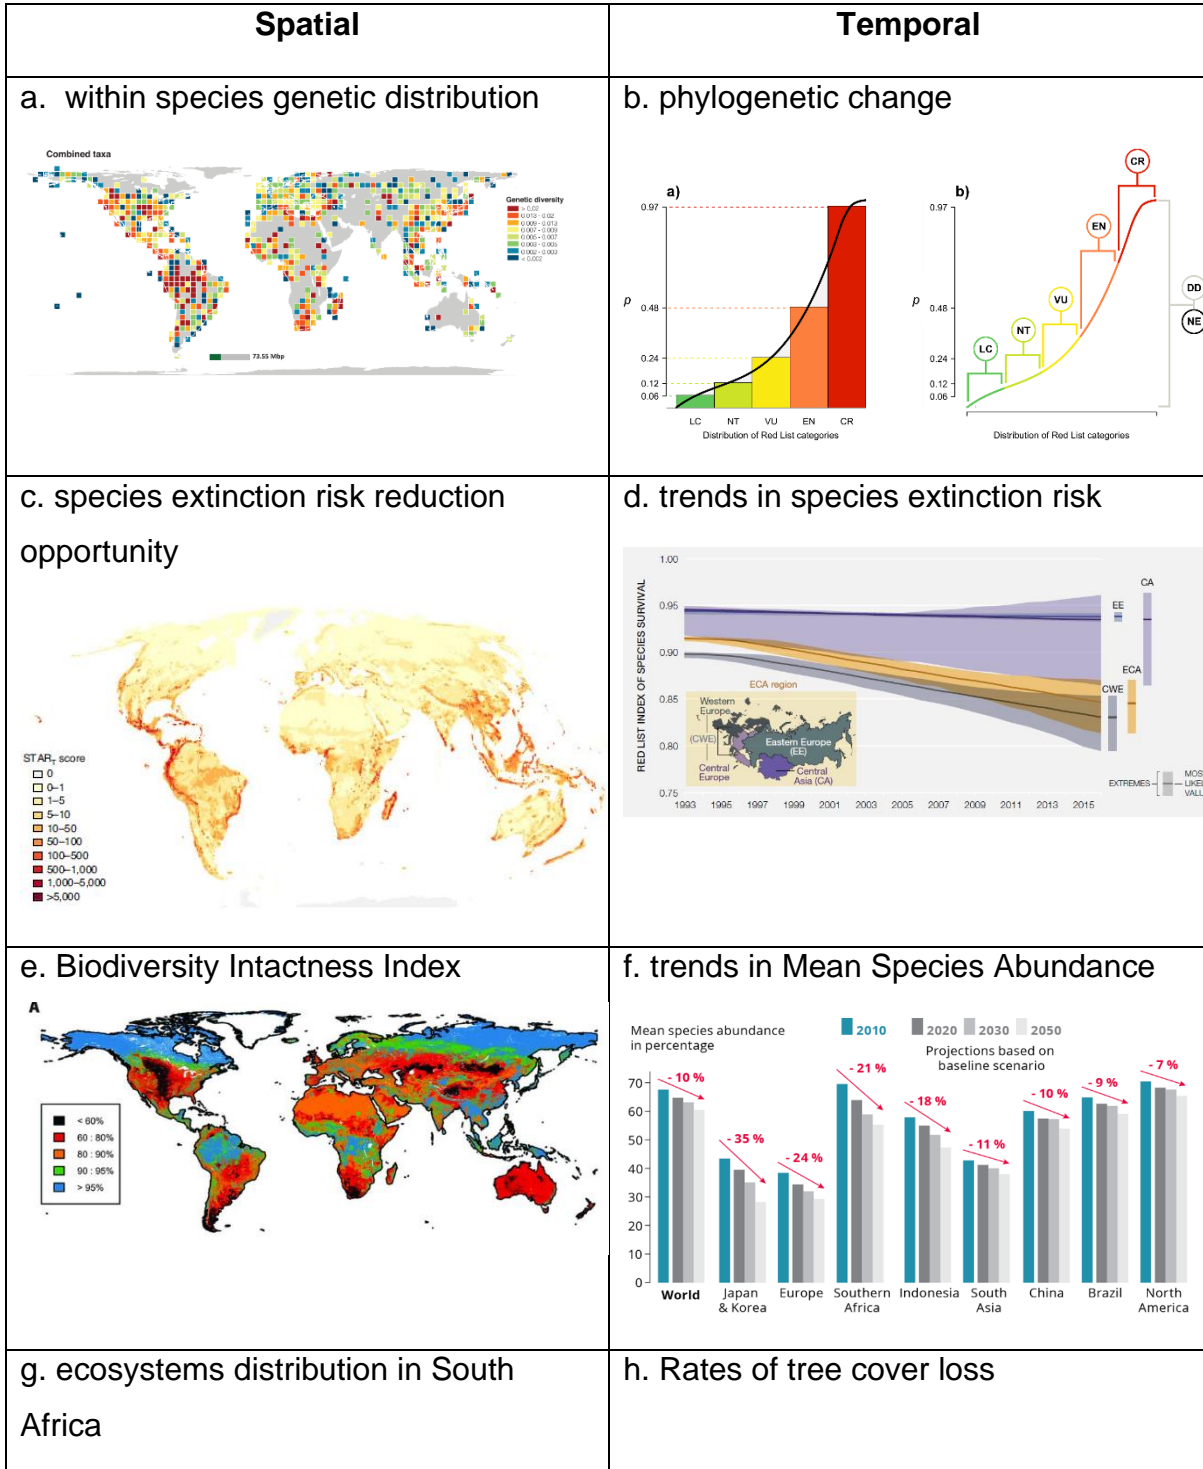

506 Metrics of ecosystem condition directly calculated using remote sensing are difficult,  
507 so they are often appraised indirectly to generate top-down intact metrics through  
508 proximity to pressures (e.g., 83). However, measures such as tree canopy height  
509 (93), or radar-based forest condition assessments (94), can deliver metrics of  
510 condition for forest ecosystems (83, 95). Another way to calculate ecosystem  
511 condition uses the intactness of species assemblages. The [PREDICTS](#) database  
512 contains 376,992 records of site level species assemblages, which is used create a  
513 Biodiversity Intactness Index (BII; 96, 97) that presents an estimated percentage of  
514 the original number of species and their abundance that remains following changes  
515 in land use. A similarly modelled index of biodiversity assemblage intactness is the  
516 mean species abundance (MSA) metric (98, 99).

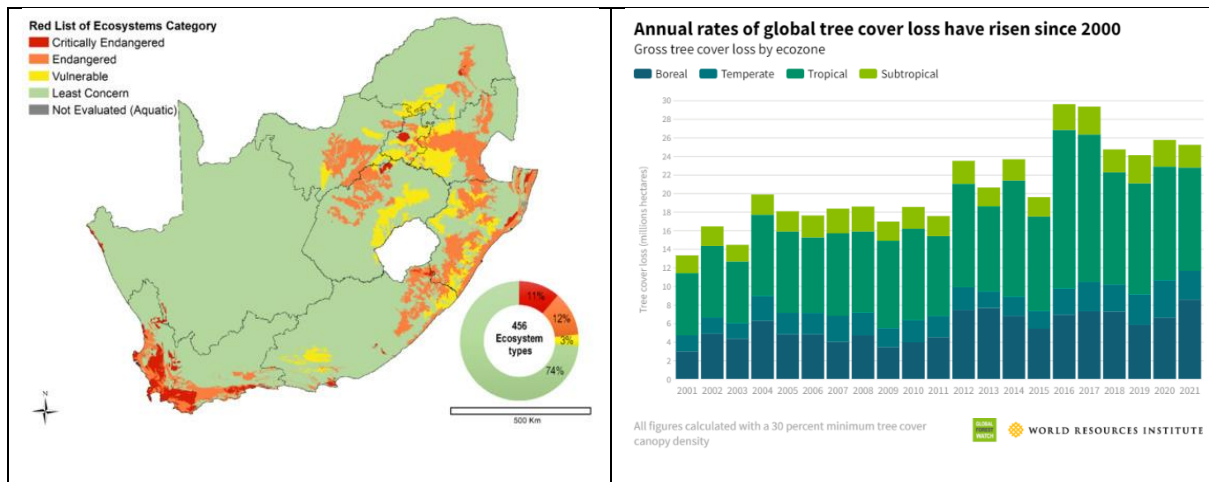

517 One of the largest programmes for assessing ecosystem condition that uses a  
518 nationally driven approach and that links to a globally agreed methodology is the  
519 IUCN Red List of Ecosystems (100–103). This is gradually developing worldwide  
520 assessments of the state of ecosystems, in terms of their risk of collapse and was  
521 incorporated into the GBF as headline indicator A1. In turn, these will allow

522 derivation of bottom-up metrics of biodiversity significance at the ecosystem level

523 (e.g., 104).

524

525 **Figure 4:** Spatially mapped and temporal metrics of the three elements of  
 526 biodiversity state.

527 Figure 4a adapted from (47); reprinted with permission from AAAS. Figure 4b adapted from (105).

528 Figure 4c reproduced with permission from (40); copyright Nature Ecology & Evolution. Figure 4d

529 reproduced from (106); copyright IPBES. Figure 4e adapted from (97); reprinted with permission from

530 AAAS. Figure 4f adapted from (107); copyright OECD. Figure 4g adapted from (108); CC-BY. Figure

531 4h reproduced from Global Forest Watch (82, 109); CC BY 4.0. The boundaries and names shown

532 and the designations used on these map do not imply official endorsement or acceptance by the

533 United Nations.

534 **Metrics of state of genetic diversity.** a. Within species genetic diversity (47),

535 showing that sampling of within species genetic diversity is patchy globally and the

536 available data are not really sufficient to be used for decision making or the creation

537 of indexes or for conservation planning. b. EDGE phylogenetic index (105), showing

538 that there is a lot of unique genetic history in species of increasing risk of extinction

539 **Metrics of species state.** c. Species Threat Abatement & Restoration metric (40),

540 showing the location of numbers of species whose extinction risk can be reduced by

541 actions to reduce threats d. Red List Indices for Europe & Central Asia (106),

542 showing how changes in the threat status for species can be used to determine

543 progress towards (or away from) extinction.

544 **Metrics of ecosystem state based in indices:** e. Biodiversity Intactness Index (BII)

545 (97), showing how the assemblage of biodiversity has changed from a historical

546 baseline situation. f. Projected trends in Mean Species Abundance (MSA) over time

547 (107), showing how changes in assemblage composition has changed (negatively)

548 over time in various regions of the world

549 **Metrics of ecosystem state based on assessments of area and condition of**  
550 **individual ecosystems.** g. Risk of ecosystem collapse for different ecosystems in  
551 South Africa (108), with ecosystem classification based on (110), showing regions of  
552 that country where the ecosystems are threatened and on a progression to collapse. h.  
553 Global trends in tree cover loss (82, 109), illustrating one of the ecosystems that can  
554 be monitored from space to illustrate global declines in cover in different parts of the  
555 world.

556

## 557 **4.2 Biodiversity pressure metrics**

558 Conservation efforts often focus on reducing pressures to reduce biodiversity loss  
559 and ultimately facilitate improvements in the state of biodiversity (111). The creation  
560 of biodiversity pressure metrics facilitates decision-making in two ways: (i) To assess  
561 the kinds of pressures that need to be addressed to improve the state of biodiversity  
562 (i.e. planning) and (ii) to assess how effective actions have been in reducing  
563 pressures (i.e. monitoring). Some metrics include a combination of state and  
564 pressure elements; notably, many metrics and indicators of biodiversity state can be  
565 disaggregated to yield indicators of specific pressures. Annex 1 contains many  
566 examples of metrics of pressure that affect all aspects of biodiversity. These include  
567 metrics of hunting, pollution, greenhouse gas emissions, air pollution, expansion of  
568 invasive alien species, logging or many other human activities.

### 569 **4.2.1 Pressure on genetic diversity**

570 No distinct metrics have been developed to measure pressures on biodiversity at the  
571 level of genetic diversity.

### 572 **4.2.2 Pressure on species**

573 Metrics of pressures on species can be disaggregated from IUCN Red List database  
574 derived metrics (112, 113) (Figure 6), for example the Species Threat Abatement  
575 and Recovery (STAR) metric (40, 114). Documentation against the standard Threats  
576 Classification Scheme (115) is required for all IUCN Red List assessments, and so  
577 STAR can be perfectly disaggregated as a metric of the opportunity to reduce  
578 extinction risk by mitigating any given threat. Another approach to measuring the  
579 impact of land use change pressure on species within the IUCN Red List is the

580 “persistence score” or LIFE metric developed by Duran et al. (66). This uses IUCN  
581 Red List data, but extinction risk is calculated in relation to both the original extent of  
582 habitat and the extent of remaining habitat, rather than from the IUCN categories  
583 directly, and all species (including those classified as Least Concern (LC)) are  
584 included (116). The list can be disaggregated to provide a pressure metric for the  
585 threats contributing to land use change.

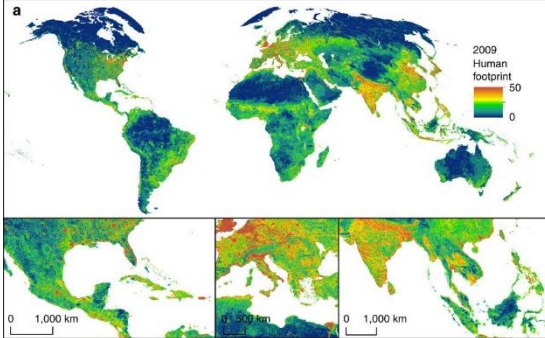

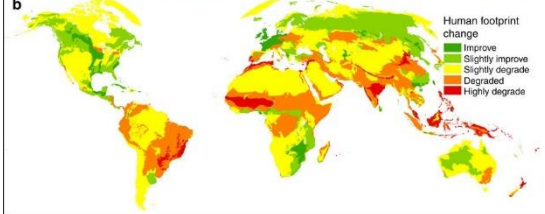

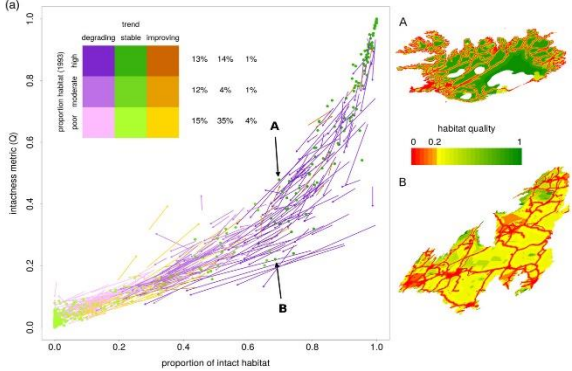

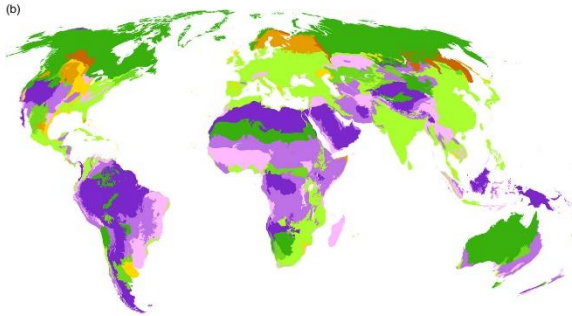

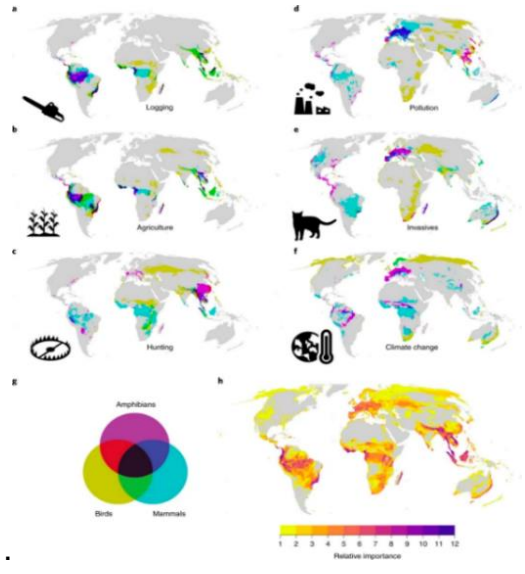

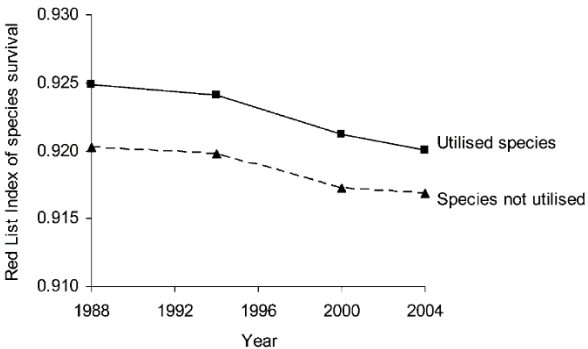

586 Specific pressures, such as sustainable and unsustainable use of species from  
587 hunting, fishing, harvesting and wildlife trade, can also be measured using the IUCN  
588 Red List (117), while metrics of species in trade can be calculated using UNCTAD  
589 databases through the Biotrade Initiative (Annex 1). IUCN Red List data can also be  
590 used to create maps of the spatial variation in extinction risk globally, which provide  
591 a proxy measure of the pressures facing species (78, 118). Specific disaggregation  
592 of the Red List Index (RLI; 67) show trends in aggregate extinction risk to species  
593 driven by particular pressures, such as unsustainable utilisation, pollution or invasive  
594 alien species, using data on the factors causing individual species to improve or  
595 deteriorate in status sufficiently to qualify for lower or higher Red List categories.

#### 596 **4.2.3 Pressures on ecosystems**

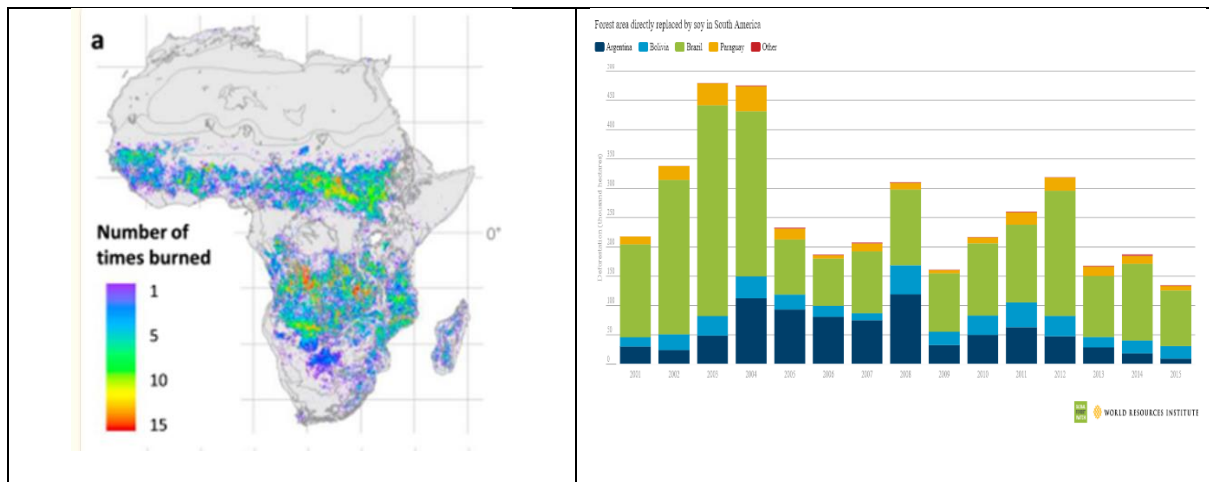

597 The most common metrics of pressure on ecosystems are those that measure a  
598 decline in ecosystem area due to land use change. Metrics that measure a decline in  
599 ecosystem condition due to pressures are also commonly developed.

600 Combinations of different remotely sensed data layers on human pressures on  
601 biodiversity have allowed the development of indices of pressure, for example the  
602 Human Footprint Index (119–122) (Figure 5), and Human Modification Index (123),  
603 which can be disaggregated into their component threats. Other metrics categorise  
604 land based on their extent of pressure, such as Low Impact Areas (124), Natural and  
605 Modified Habitat (125) and anthropogenic biomes (126, 127). The [GLAD](#) alerts (128)  
606 are pressure indicators for deforestation events available on the Global Forest Watch  
607 platform are used by non-government and civil-society organisations (as well as  
608 governments) to target interventions to address illegal deforestation and forest  
609 degradation.

610

Spatial	Temporal
<p data-bbox="252 271 730 353">a. distribution of human footprint index</p>  	<p data-bbox="778 271 1295 353">b. changes in human footprint within ecoregions</p>  
<p data-bbox="204 1126 746 1160">c. distribution of pressures on species</p> 	<p data-bbox="778 1126 1327 1209">d. trends in species populations due to different pressures</p> 
<p data-bbox="204 1789 746 1872">e. fire intensity in Africa as a potential pressure on ecosystems and species</p>	<p data-bbox="778 1789 1327 1872">f. trends in deforestation linked to agriculture</p>

611 **Figure 5.** Spatial and temporal examples of biodiversity pressure metrics.

612 Figure 5a adapted from (149, 150); CC BY 4.0. Figure 5b adapted from (129); CC BY. Figure 5c  
 613 adapted from (113); CC BY 4.0. Figure 5d reproduced with permission from (130); copyright  
 614 Cambridge University Press. Figure 5e reproduced from (131); CC-BY-NC-ND. Figure 5f reproduced  
 615 from Global Forest Watch (132); CC BY 4.0. The boundaries and names shown and the designations  
 616 used on these map do not imply official endorsement or acceptance by the United Nations.

617 **Pressures on ecosystem condition.** a. Human Footprint Index (119), showing how  
 618 a series of remotely-sensed layers can be combined to give a spatial metric of the  
 619 degree of human pressure on nature (noting that some pressures like hunting or  
 620 climate change are not included in this metric). b. Changes in pressure within  
 621 ecoregions (129), showing how human footprint change data can be used to  
 622 measure changes in pressure across the more than 800 ecoregions in the world.

623 **Pressure on species.** c. Distribution of pressures on species using data derived  
 624 from the IUCN Red List of threatened species (113), showing that there are spatial  
 625 patterns in how pressures on species are distributed globally – facilitating  
 626 conservation decision making to reduce these pressures. d. Red List Indices for  
 627 utilised bird species in comparison to those that are not utilised by people (130),  
 628 showing that there is a similar progression towards extinction for species that are  
 629 both used or not used.

630 **Pressures on ecosystems.** e. Number of times areas in Africa burned 2002–2016  
 631 (MODIS 500-m) (131), showing areas of Africa where vegetation is naturally fire-  
 632 prone but also showing that some areas are burning almost every year which is a  
 633 higher frequency than the natural situation without human-set fire. f. trends in the  
 634 loss of forest cover due to the pressure of agriculture in some South American

635 countries (132), showing large annual variation in the amount of forest lost to  
636 agriculture in different countries.

637

### 638 **4.3 Biodiversity response metrics**

639 Most of the response metrics listed in Annex 1 relate to the GBF, and many consist  
640 of counts of the numbers of countries or other entities that have developed a policy  
641 or otherwise responded to the biodiversity crisis. While essential, these metrics are  
642 necessarily simplistic and contain limited information for further decision-making.  
643 Here we focus on metrics that facilitate a richer understanding of how responses  
644 might affect biodiversity state or reduce pressures.

645 Metrics of responses to the conservation of genetic diversity typically relate to the  
646 numbers of species in long term storage facilities (seedbanks and tissue banks) or in  
647 botanical gardens or zoos. These are further elaborated for domesticated species  
648 where the genetic diversity of crops and domesticated animals is carefully monitored.  
649 Hoban et al. (50) also proposed measurement of “the number of species (and  
650 populations) monitored using DNA-based methods”, as a response metric (i.e.,  
651 through measurement of knowledge).

652 The World Database on Protected Areas (133) and on Other Effective Area-based  
653 Conservation Measures (134) contains information on those areas set aside for  
654 conservation, sustainable use or other reasons that achieve biodiversity goals.  
655 Response metrics derived from these databases include the area of ecosystems and  
656 Key Biodiversity Areas protected over time (135) – used as GBF headline indicator  
657 3.1 – and the condition of ecosystems within protected areas (136).

658 There are a suite of diverse metrics on protected area connectivity (i.e., ProtConn,  
659 ProNet, PAI, PARC, ConnIntact). Theobald et al. (137) explains some of the  
660 differences between these metrics and how they can be used. Gaps remain in our  
661 understanding of where connectivity conservation is most critical including  
662 measuring key aspects of connectivity related to migratory connectivity across  
663 terrestrial, coastal/marine, and inland waters.

664 The World Database on Key Biodiversity Areas contains species, site, threat and  
665 habitat data from over 16,000 sites of significance for the global persistence of  
666 biodiversity (138) (Figure 6). KBA data underpin metrics on the conservation

667 responses at more than 4000 sites and on the degree to which KBAs are covered by  
668 protected areas and Other effective area-based conservation measures (OECMs),  
669 which is used by the SDGs – specifically tracking protected area coverage of KBAs  
670 for marine (SDG indicator 14.5.1), terrestrial and freshwater (SDG indicator 15.1.2),  
671 and mountains (SDG indicator 15.4.1) – and also by the CBD and other MEAs as a  
672 response measure.

673 Although more typically used to measure species state, and to understand pressures  
674 on species, indices derived from the IUCN Red List can also be informative about  
675 the potential or actual outcomes from responses. For example, the Realised STAR  
676 scores (40) quantify the reduction in global extinction risk achieved through  
677 implementation of responses. Similarly, the LIFE metric (66, 116) can be used to  
678 measure species responses resulting from restoration.

679

#### 680 **4.4 Biodiversity benefits**

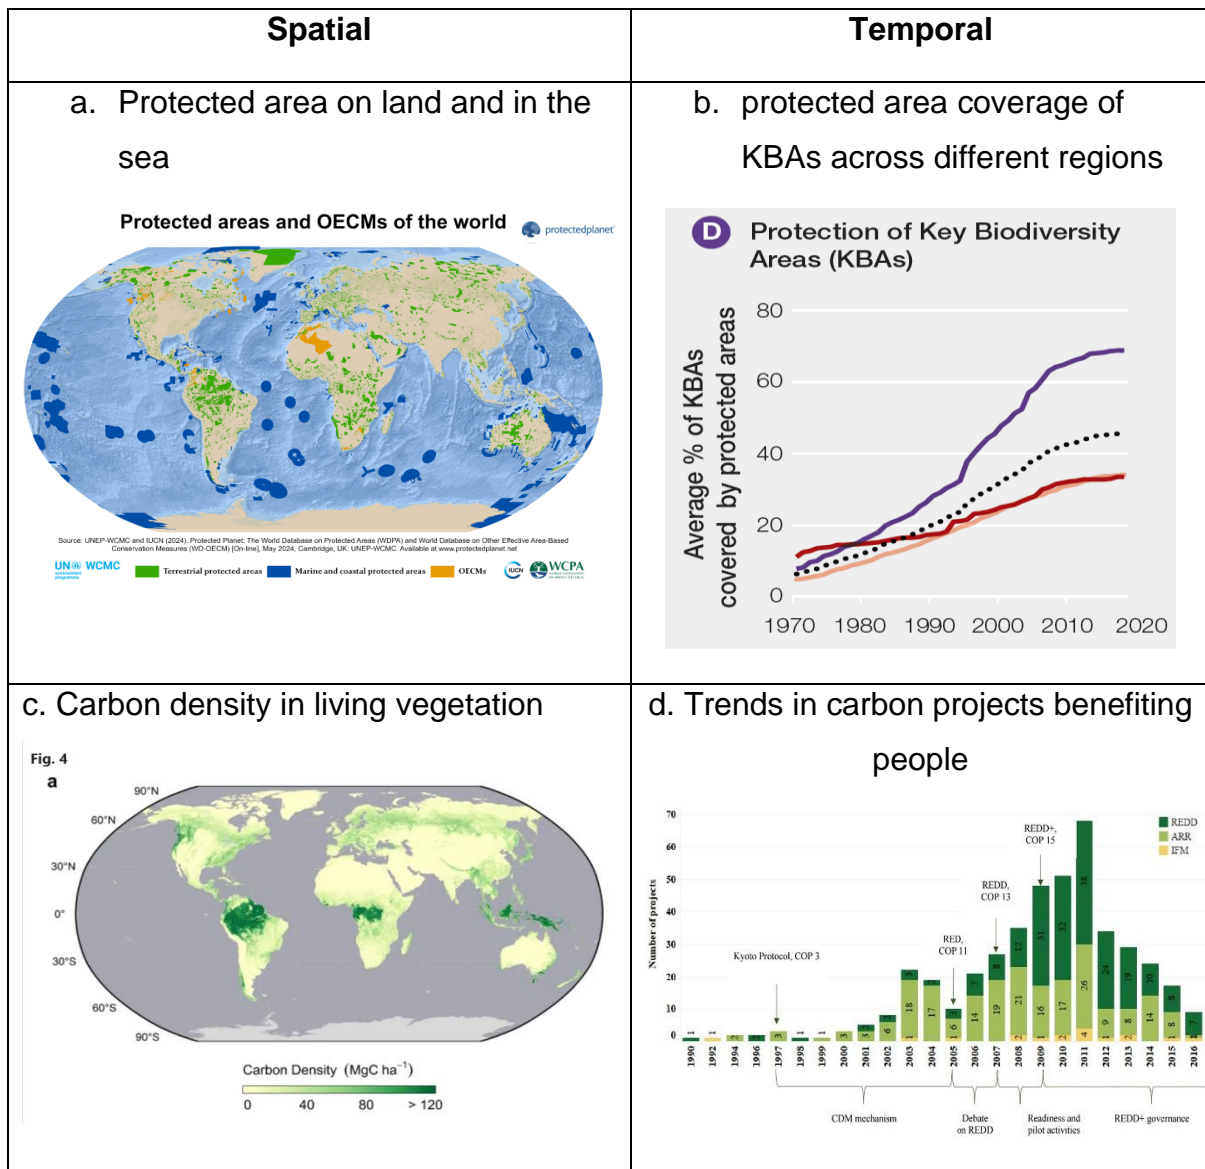

681 People benefit from biodiversity through the ecosystem services (nature's  
682 contributions to people) that it provides, such as regulation of water supply, provision  
683 of food, pollination of crops, etc. (139–141). These benefits are the direct and  
684 indirect contributions from ecosystems (underpinned by natural capital (e.g., 142)).  
685 The potential ecosystem service is the benefit that could be obtained, but there are  
686 no people to use the service, while the realised service is the actual benefit  
687 experienced or delivered to people.

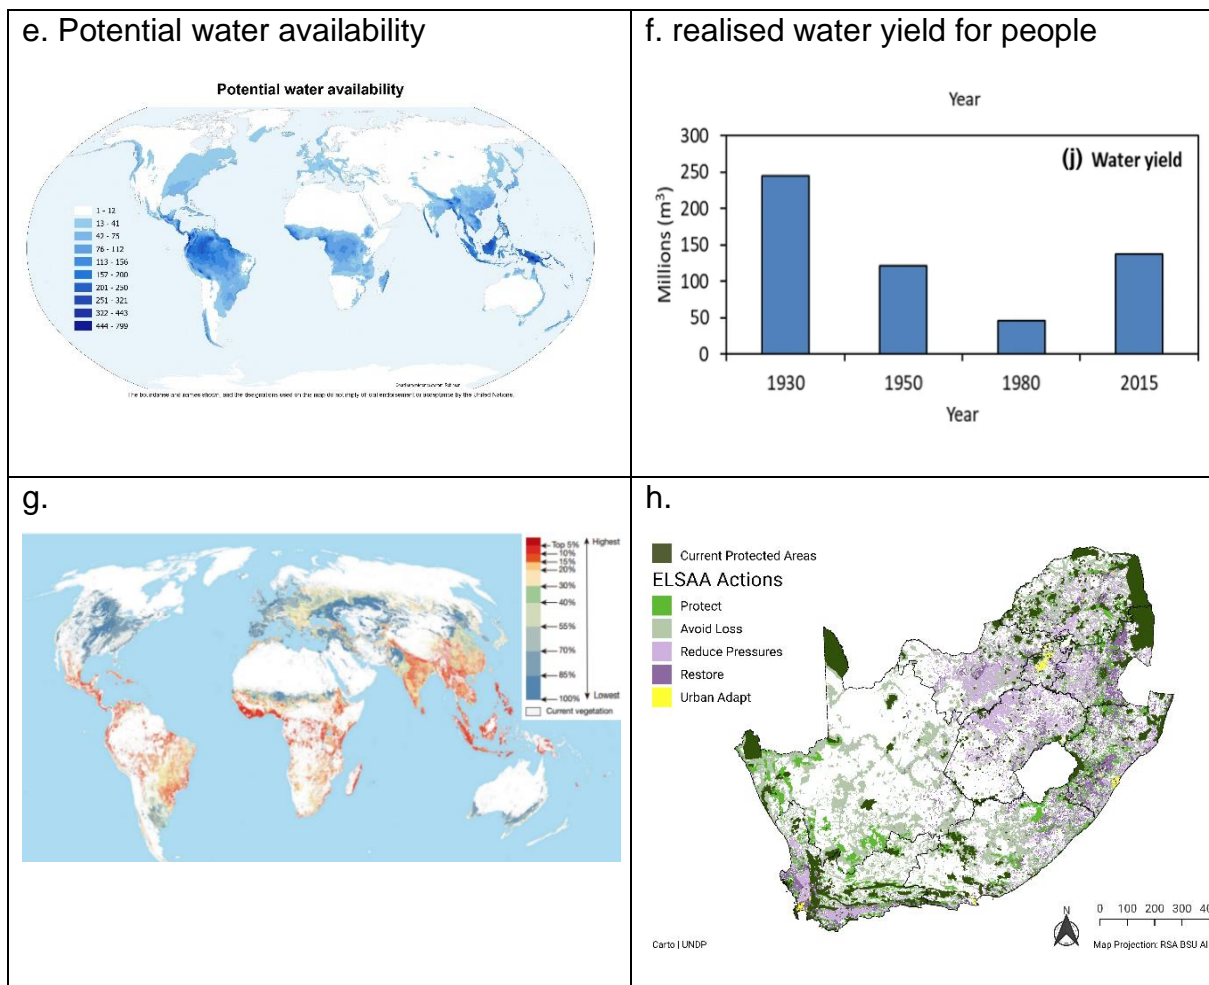

688 Metrics exist to measure both potential and realised ecosystem service benefits and  
689 help understand the consequences of biodiversity loss on people (examples in Table  
690 S6). Ecosystem service assessments often use land use / land cover (LULC) maps  
691 that are then linked to attributes of value to people to develop models of realised  
692 ecosystem services flows (143–147). This means that many ecosystem service  
693 metrics broadly reflect the patterns of land cover, land use and human population  
694 density and consumption preferences. Changes in land cover, human population,  
695 use of natural capital, and sustainability of supply can all determine how ecosystem  
696 service flows continue over time. If the benefit realised is not sustainable, it will  
697 degrade the underlying natural capital leading to a loss of benefits over time. For  
698 species, abundance metrics in combination with demographic data can help

699 determine the numbers of wild animals or plants that can be harvested for human  
 700 use.

701 Few global ecosystem service layers are temporal. Indeed, it is rare for ecosystem  
 702 service provision to be tracked over time. An exception is the tracking of change over  
 703 time in biomass carbon as this has been linked to temporal land cover maps allowing  
 704 carbon sequestration and emissions to be calculated (148), which are relevant for  
 705 the ecosystem service of climate regulation. Detailed ecosystem service status  
 706 updates are available at regional to local scales, for example for Africa (149), Europe  
 707 (150), USA (151), and numerous papers for countries or parts of countries, such as  
 708 Uganda (152), Mozambique (153), Tanzania (154) (Table S4, Figure 6)

709

710 **Figure 6:** Examples of response and benefits metrics

711 Figure 6a adapted with permission from Protected Planet (135). Figure 6b reproduced from (141);  
 712 copyright IPBES. Figure 6c adapted from (155); CC BY 4.0. Figure 6d reproduced from (156); CC-BY-  
 713 NC-ND. Figure 6e data provided by (157). Figure 6f adapted from (158); CC BY 4.0. Figure 6g

 715 UNDP. The boundaries and names shown and the designations used on these map do not imply  
 716 official endorsement or acceptance by the United Nations.  
 717

718 **Response metrics (protected areas).** a. Protected areas globally (135), showing  
 719 those areas of land and sea that have been declared mainly by governments for  
 720 conservation purposes, facilitating a calculation of the area of land and sea  
 721 protected. b. Changes in the percentage protection of Key Biodiversity Areas by  
 722 protected areas for developing and developed countries, compared to globally  
 723 (dotted line) (141), showing that key sites for biodiversity conservation are increasing  
 724 being conserved within protected areas over time but with difference between  
 725 developed and developing countries

726 **Ecosystem service metrics.** c. Biomass carbon distribution globally (155), showing  
727 a concentration of biomass carbon in the world's forests, especially tropical forests.  
728 d. Trends in biomass carbon projects benefiting people (REDD+ and others) (156),  
729 showing a peak in new projects focusing on carbon around 2010 with an apparent  
730 decline after then. e. Water availability (157) showing those areas where there is at  
731 least a seasonable abundance of water, especially in some temperate regions and  
732 tropical wet areas. f. changes in realised water for people following agricultural  
733 intensification and partial reforestation in Dorset, UK, 1930-2015 (158), showing a  
734 decline in realised water availability due to agricultural intensification up to the  
735 1980s, followed by a recovery since that time.

736 **Response metrics (restoration and planning).** g. Ranked restoration priority areas  
737 (159), showing that there are parts of the world of a much greater priority for  
738 restoration to achieve nature outcomes than other areas. h. Systematic plan of  
739 nature positive areas in South Africa (160), highlighting a ranked set of areas  
740 according to different measures that are conservation priorities for that country.

#### 741 **4.4.1 Multidimensional indices**

742 Some metrics are multidimensional as they seek to present information covering  
743 biodiversity state and pressure, and sometimes also responses or benefits (Annex 1;  
744 Figure 7). An ecosystems example is the Ecosystem Integrity Index (161) that  
745 contains measures of ecosystem condition and pressure. Another index measures  
746 the capacity of ecosystems to retain species under the pressure of climate change -  
747 the Bioclimatic Ecosystem Resilience Index (BERI; 162). Similar metrics have been  
748 developed within the framework of [ecoregions](#) globally (129, 163), and regionally  
749 (e.g., 164).

750 Further efforts have also been made to try and simplify the problem of multiple  
751 metrics —by developing complex indices that represent different dimensions of  
752 pressure, state, response within a single index. Examples of tools and stand-alone  
753 indices that are being used by governments or business include the Local Ecological  
754 Footprint Tool ([LEFT](#)), which takes 7 input data layers and processes them into a  
755 map of “relative ecological value” (165) (Figure 7).

756 Another is the Multidimensional Biodiversity Index (MBI), which aims to combine  
757 measures of the biodiversity state and its contribution to people in a multidimensional

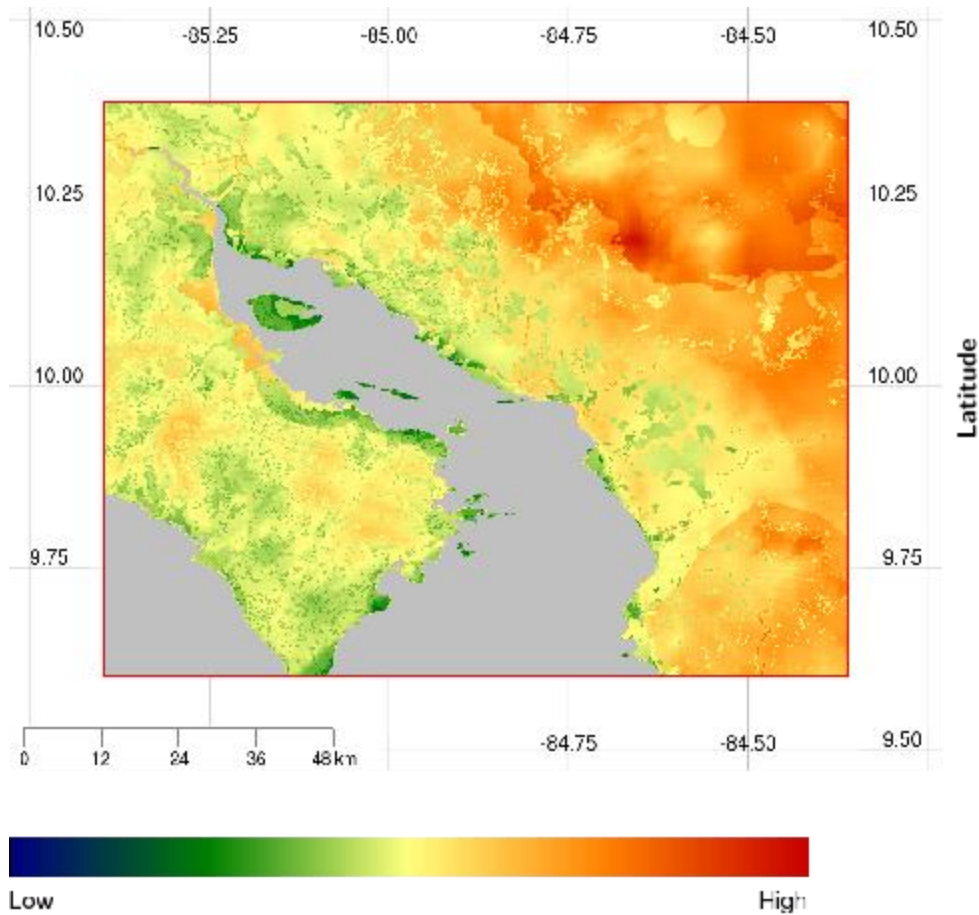

758 ecological and social approach that considers the specifics of each national context.  
759 This allows countries to develop policies and take actions that consider the  
760 importance of safeguarding biodiversity for their sustainable development and well-  
761 being (166). This approach is analogous to indices such as the Human  
762 Development Index (HDI), the Multidimensional Poverty Index (MPI) and others. For  
763 business use, Environmental, Social and Governance (ESG) ratings are based on  
764 composite metrics that are built using different data inputs.

765 Multidimensional indices are often controversial. Such indices tend to treat different  
766 facets of biodiversity equally, are based on subjective weighting, are based on  
767 arbitrary scores, have an inconsistency in spatial scale, have inconsistency in the  
768 timescales of their datasets or may combine measures. This makes it nearly  
769 impossible to understand what drives trends without breaking the metric down into its  
770 constituent parts (167). Nevertheless, there remains a demand from both  
771 governments and business for such indices and they may play a role in  
772 communication or high-level decision making.

773 As examples, the Local Ecological Footprint Tool (LEFT) providing an example map  
774 of “relative ecological value” (165), showing a complex index of nature values that  
775 has been used by some companies for decision making (Figure 7).

776 **Figure 7:** Examples of multidimensional indices.

777 a) Visualization of the Local Ecological Footprint Tool (LEFT; 165), providing an  
778 example map of “relative ecological value” (168), showing a complex index of  
779 nature values that has been used by some companies for decision making.  
780 Figure reproduced with permission from (168).

785

786

787

788

789

- b) A hypothetical example of a Multidimensional Biodiversity Index score (166). Each bar represents a biodiversity objective score ranging from 0 to 1, calculated from a series of indicators. The values can be considered separately or aggregated to obtain a country or region's overall score (in this case 0.76). The green bars show the Biodiversity State Sub-index (BI) dimensions and objectives, while the blue bars show the Biodiversity Contribution to People Sub-index (BCPI) dimensions and objectives. Unpublished figure by Ana Ramos Rodrigues.

**MBI score: 0.76**

790

## 791 **5 Towards a minimum set of metrics**

792 Some representatives of governments or business have highlighted the complexity  
793 of biodiversity metrics and requested simplification. These requests mirror those for  
794 the climate where the complexity of the climate system has been reduced to a focus  
795 on measuring the three goals of the Paris Agreement: greenhouse gas emissions  
796 (especially CO<sub>2</sub>) and staying below a 1.5°C temperature rise above pre-industrial  
797 levels; climate change adaptation; and climate financing.

798 For biodiversity, a single metric is seen by many as scientifically indefensible (see  
799 169). This is because a) we can measure biodiversity at different levels – e.g. genes,  
800 species and ecosystems - that are all unevenly distributed globally and undergoing  
801 different temporal trends; b) we can measure biodiversity in terms its benefits – for  
802 example, its direct contributions to people, its underpinning role in ecosystems, or its  
803 intrinsic value; c) we can prioritise biodiversity according to various measures of its  
804 rarity or extinction risk (or we can ignore that and measure it in absolute terms).

805 There is no right or wrong choice in any of these and it depends upon the application  
806 as to which is the most suitable approach for measuring biodiversity value.

807 Thus, rather than proposing a single metric, which could not cover all aspects of  
808 biodiversity for all user groups, we have pooled our knowledge to identify a small  
809 number of metrics to address current needs (Table 2), building off previous papers  
810 (170, 171).

811 Criteria we used to identify this set were: a) ideally included as SDG 14 & 15  
 812 indicators and/or GBF headline indicators (highlighted in red in Table 2), b) published  
 813 metric with available methodology and data, c) data flows exist to update the metric,  
 814 d) responsible institution(s) committed to maintain and update the metric for at least  
 815 10 years, e) available for all countries and freely accessible for government decision  
 816 making and f) established way to use the metric for commercial decision-making.  
 817

	Genes	Species	Ecosystems
State	EDGE <sup>1</sup>	STAR	Extent of natural ecosystems <sup>1</sup>
(significance)		<u>RLI</u>	RLE
State	-	LPI <sup>1</sup>	BII
(intactness)			MSA/ PDF/cSAR
Pressure	-	STAR <sub>T</sub>	HFI
Response	-	STAR <sub>T and R</sub>	<u>PA coverage</u>
		GSSI <sup>1</sup>	
Benefits	-	-	Forest Carbon Flux

818 **Table 2.** Proposed core set of metrics for measuring state, pressure, response and  
 819 benefits aspects of biodiversity (species, ecosystems and genes).

820 **Key:**

821 Genes: EDGE = Evolutionarily Distinct and Globally Endangered Index

822 Species: STAR = Species Threat Abatement and Restoration metric; RLI = Red List

823 Index and associated disaggregations; LPI = Living Planet Index and associated

824 disaggregations, STAR<sub>T</sub> = threat abatement component of STAR, which can be

825 disaggregated by threats; STAR<sub>R</sub> = restoration component of STAR; GSSI = Green

826 Status of Species Index. Ecosystems: Extent of natural ecosystems = trends in

827 habitat extent derived from remote sensing; RLE = Red List of Ecosystems Index; BII

828 = Biodiversity Intactness Index; MSA = Mean Species Abundance; PDF = Potentially

829 Disappeared Fraction; cSAR = Countryside Species–Area Relationship; HFI =  
830 Human Footprint Index; PA coverage = protected area coverage and associated  
831 disaggregations; Forest Carbon Flux = biomass carbon flux.

832 **In red and underlined**: SDG and GBF headline indicators. **In red**, GBF headline  
833 indicators.

834 <sup>1</sup> = These metrics may not meet criteria (e) or (f)

835

## 836 **6 Discussion**

837 We have shown that a diverse array of biodiversity metrics is currently available,  
838 covering different aspects of biodiversity, which relate to measures of pressure,  
839 state, response and benefits. However, we have also shown that there are large  
840 numbers of metrics developed for different use cases and the field remains  
841 confusing for many users. Our summary of suggested metrics, drawing from existing  
842 intergovernmental decisions, boils the large numbers of metrics down to a handful. In  
843 this discussion we cover some of the issues that will affect the development and  
844 maintenance of metrics for decision-making over the medium term. We then  
845 conclude with some core findings and a way forward.

846

### 847 **6.1 Data availability**

848 For most metrics, the limited availability of field-level biodiversity data and data that  
849 are regularly updated are significant constraints to the quality of the metric. For the  
850 species data, most of the available metrics use a handful of data sources. These are  
851 typically biased towards vascular plants and vertebrates – especially birds – and lack  
852 depth for fungi and invertebrates. Available data are also geographically biased, with  
853 significant gaps in global coverage (Figure 3). Apps on smart phones are allowing  
854 data collection in some poorly studied parts of the world to rapidly accelerate, but  
855 there are still regions with almost no data, and validation of data, especially for  
856 poorly-known taxa, is a problem.

857 The increasing numbers of satellites in orbit and the diversity of products they  
858 deliver, means there is a rapidly expanding array of metrics being produced using

859 remote sensed data (see Annex 1 for lists). However, very few products fit the needs  
860 of specific end-users in the biodiversity community, and biodiversity scientists are  
861 often required to adapt existing products to their needs (172). Despite the hopes of  
862 the biodiversity metrics community, this situation has not improved much over the  
863 last two decades. But the new generation of landcover products (e.g., 173–176), with  
864 AI-enabled learning and rapid update, may – if linked to ecological and biodiversity  
865 expertise – provide ways forward in coming years. However, this cannot replace the  
866 need for metrics derived from in situ monitoring.

867

868 **Figure 3:** Biodiversity data records per one degree grid globally (Data provided by  
869 GBIF.org)

870

## 871 **6.2 The role of civil society**

872 Civil society has an important role to play in contributing data to create biodiversity  
873 metrics and indicators (177, 178). For example, civil society is particularly active in  
874 the use of citizen science smart-phone and web-based data collection tools such as  
875 [iNaturalist](#), [eBird](#) and the [Lost Ladybug Project](#). Occurrence data generated through  
876 these tools, as well as [camera traps](#), [bird feeders](#), [smart listening devices](#), [e-DNA](#)  
877 [surveys](#) and [Environmental Impact Assessments](#) are typically integrated with  
878 museums and herbaria through platforms such as [GBIF](#) (179).

879 Although spatial coverage of these tools is variable, and quality may vary depending  
880 on how data are ground-truthed/validated, they are starting to deliver the best

881 available data on many species, and this trend seems likely to continue. Statistical  
882 methods are advancing to deal with some of the data limitations of these approaches  
883 (180). Civil society can also be involved in evaluating ecosystem services (e.g., 181)  
884 using tools like [i-Tree](#) developed by the USDA Forest Service. Substantial attention  
885 is also now being devoted to advancing application of indigenous and local  
886 knowledge in support of biodiversity metrics, for example in the IUCN Red List (182).  
887

### 888 **6.3 The need for sustainable financing**

889 For the main metrics in use, and new ones that will be developed, there is a crucial  
890 need for *ongoing* investment in maintaining the flows of data and aggregation  
891 capacity to continue to deliver the metric (183). There is also a need to ensure that  
892 core metrics are backed by institutional commitments to deliver them to agreed user  
893 communities and that work continues to make their production easier, faster, and  
894 cheaper – especially through the use of new technologies. These are key factors in  
895 sustainability and utility for government or business decision-making.

896

### 897 **6.4 Factors driving the uptake of metrics by governments**

898 Governments require metrics and indicators that can help them to deliver national,  
899 and regional policy commitments (such as the EU, African Continental Free Trade  
900 Area (AfCFTA), East African Community etc), or globally agreed commitments such  
901 as those defined by Multilateral Environment Agreements (MEAs) such as the  
902 Sustainable Development Goals, GBF, UNFCCC, CITES, UNCCD and the Ramsar  
903 Convention on Wetlands.

904 Biodiversity metrics are much more likely to be taken up by governments if they are  
905 part of a global or regional framework and are possible for the country to collect and  
906 report against. Globally generated metrics, often housed and created by UN  
907 agencies, NGOs or universities, have the advantage that they have standardised  
908 methods and are often comparable across space and time. However, there are often  
909 challenges with using these global metrics at national scales. For example,  
910 definitions (such as land use/cover classifications) often do not align between global  
911 and national users, or with definitions used by business laws and frameworks. For  
912 example, the definition of natural habitat/ecosystem within the International Finance

913 Corporation's (IFC) Performance Standard 6 (184) and the EU Habitats Directive  
914 (Council Directive 92/43/EEC) differ and are sometimes conflicting. Academic or  
915 NGO-generated metrics may lack political legitimacy at the national level as they are  
916 not created or endorsed by governments and may have no institutional mandate for  
917 maintenance into the future. These kinds of challenges risk inconsistency between  
918 global and national metrics, preventing meaningful comparisons and hence hindering  
919 overall assessments of the status and trends in biodiversity. In turn, this may limit the  
920 reliability of communications to decision-makers and the public on the situation  
921 facing biodiversity around the world.

922 A political balancing act is therefore required to create systems where nationally  
923 generated metrics (by government, citizen scientists or indigenous peoples and local  
924 communities) can be used alongside globally or regionally generated metrics. This is  
925 illustrated in the periodic [Global Biodiversity Outlooks](#), [Global Environmental](#)  
926 [Outlooks](#), and [Global Forest Resource Assessments](#). It is also seen in the  
927 implementation of deforestation-free supply chain laws, which although developed  
928 for good reasons of climate and nature loss, can cause concern and political  
929 controversy in countries of commodity origin.

930

## 931 **6.5 Factors driving the uptake of metrics by businesses and trade** 932 **systems**

933 There is interaction between national/regional/international policy and the responses  
934 of business and trade systems (185). First, businesses need to reduce current or  
935 possible future transition risks, such as loss of competitiveness and earnings due to  
936 a failure to align with the requirement of policies and laws (186). These could arise  
937 not only from regulatory changes, but also from societal and investor pressures to  
938 transform approaches to reduce impacts on biodiversity. Second, businesses also  
939 increasingly recognise the scale of nature-related physical risks and the  
940 opportunities relating to their own operations and the wider economy (5, 187). This  
941 includes the financial risk to businesses from the loss of biodiversity that many  
942 companies are already experiencing. Third, if not addressed, loss of biodiversity may  
943 lead to [systemic risks that prevent businesses from operating](#) at all in the future as  
944 biodiversity-based life support systems collapse (188, 189).

945 Businesses have responded to these emerging issues by participating much more  
946 actively in the negotiations around the biodiversity COPs (190, 191). To align with  
947 the GBF targets and indicators, businesses are now considering how their impacts  
948 and dependencies on biodiversity may be accounted for, how their contributions to  
949 these goals and targets can be recognised, and how to select metrics to measure  
950 these contributions. Challenges remain, for example, in relation to the required scale  
951 of analysis, with operational decisions at company scale often requiring bespoke,  
952 context-specific approaches that are intractable using global data and most web-  
953 based platforms.

954 Consensus is emerging across many of the recent assessment and disclosure  
955 standards on the need to include both metrics of company's pressures on  
956 biodiversity, as well as metrics of the state of biodiversity based on both species and  
957 ecosystems. Metrics of the state of biodiversity include those used to screen and  
958 prioritise risks to biodiversity, as well as those used to understand impacts (31).

959 Business is also heavily involved in the global commodity trading system, which is  
960 highly interconnected. This means that consumption in one country can have  
961 impacts on multiple others (185, 192). Metrics used to measure the impacts of  
962 supply chains need to be comparable between producing and consuming  
963 governments. Overall, there is a connection between 'standards' that might be  
964 applied by either producing or consuming countries and the fact that one needs to  
965 support these standards with comparable measures (193). An example system being  
966 tested by the UK government is the [Commodity Footprints](#) tool that uses the [PDF](#)  
967 [metric](#) and the species persistence score to assess impacts of commodity trading  
968 between nations (66). Additional similar systems are in development and seeking to  
969 use relevant biodiversity metrics within their system.

## 970 **7 Summary Points**

971 Following this review of biodiversity metrics, we make four summary points:

- 972 **1. Clarifying uses for many metrics.** Many biodiversity metrics are available to  
973 inform decisions regarding screening, planning, and resource allocation for  
974 countries and business. However, the large number of potential metrics  
975 confuses some users and hinders effective decision-making. Capacity to use

976 existing metrics and take appropriate decisions is often low and needs to  
977 increase.

978

979 **2. Meeting the needs of government users.** For governments, nationally  
980 generated metrics can be important to address nationally specific  
981 circumstances, as well as to create political buy-in and legitimacy, but globally  
982 consistent metrics are essential to ensure global consistency. Nested  
983 approaches which allow cross-walking between national and global  
984 approaches show promise in resolving this (194) (195).

985

986 **3. Meeting the needs of business users.** For businesses, frameworks and  
987 standards on biodiversity assessment, disclosure and target setting (e.g.  
988 TNFD, GRI, ESRS etc) provide an initial set of biodiversity metrics, but further  
989 developments of disclosure requirements and guidance will be needed.  
990 Business needs to be able to aggregate results from different locations to  
991 facilitate decision making at company or portfolio level (189). Metrics that  
992 companies use to support screening and target setting should be  
993 complemented with metrics that are responsive and amenable to regular  
994 updates that allow the company to deliver outcomes and monitor change as a  
995 result of management actions (14).

996

997 **4. Downscaling metrics to operational scales.** Many global metrics operate at  
998 resolutions of 1x1km<sup>2</sup> due to the resolution of the underlying data.  
999 Biodiversity impacts vary at small geographical scales, so metrics that can  
1000 facilitate understanding of impacts and results of responses at small scales  
1001 are needed. Metrics developers need to provide clear information about the  
1002 level of uncertainty in their metrics and the scales where they can reliably be  
1003 used.

1004

## 1005 **8 Future Directions**

1006 **1. Increasing importance of national metrics.** For international and regional  
1007 agreements there will be an increasing need for core metrics, currently largely

1008 provided by international organisations, to be calculated using agreed  
1009 standards and methods by national governments. The accelerating demand  
1010 from business (including finance, and trade related companies) means that  
1011 creating finer scaled, more frequently updated, more accurate and more  
1012 actionable metrics will be required (196).

1013

1014 **2. Agreeing a minimum set of metrics for government and business use.**

1015 Agreeing on a core set of biodiversity metrics that can work across scales and  
1016 meet the needs of multiple user groups is clearly desirable. As this review  
1017 has shown, this is not easy because biodiversity is made up of three  
1018 components and is both affected by people, managed by people and delivers  
1019 value to people. The Essential Biodiversity Variables (197, 198) provides  
1020 another set of options, but many of these proposals are not yet operational, or  
1021 available, to support decision making.

1022

1023 **3. Automation of metric calculation through and use of technology.**

1024 Considerable effort is put into building new products using the latest  
1025 technology, but these often fail to represent the world in the ways that are  
1026 useful for biodiversity conservation. For remote sensing and technology  
1027 companies, and those using AI and machine learning, the inclusion of  
1028 ecologists and biogeographers familiar with species and ecosystems would  
1029 improve the biodiversity metrics being generated.

1030

1031 **4. Generating sustainable funding for metric production.** Most areas of  
1032 society have created funding systems to provide the flows of data and metrics  
1033 that are required to take decisions. This is the case for health, economy,  
1034 education, poverty, children, climate and weather, forestry, agriculture,  
1035 fisheries, genetics, seeds. Most nature data flows are funded through  
1036 projects or rely on volunteer efforts. This is clearly not a sustainable system  
1037 and is one of the reasons for fragmentation and duplication of effort.

1038

1039

1040 **9 Acknowledgements**

1041 We thank all those who have developed biodiversity metrics over the past decades.  
 1042 This research has been funded in part by the UK Research and Innovation’s Global  
 1043 Challenges Research Fund under the Trade, Development and the Environment Hub  
 1044 (TRADE Hub) project (project number ES/S008160/1). The following people  
 1045 contributed in terms of editorial inputs to earlier drafts: From UNEP-WCMC (Andy  
 1046 Arnell, Samantha Hill, Andrea C Baquero, Alex Ross, Katherine Despot-Belmonte,  
 1047 Han Meng, Chris McOwen, Matt Jones), Stockholm Environment Institute (Amy  
 1048 Molotoks), University of Cambridge (Alison Eyres).

1077 **Table S5:** Example metrics within tools and platforms for business, trade-systems  
 1078 and financial users

<b>Business need</b>	<b>Examples of metrics relevant to business need</b>	<b>Examples of tools relevant to the business need</b>
Site, Portfolio, or Corporate level biodiversity footprint	<a href="#">Species Threat Abatement and Recovery (STAR)</a> and <a href="#">Range Rarity</a>	<a href="#">Integrated Biodiversity Assessment Tool (IBAT)</a> and <a href="#">ENCORE Biodiversity Module</a>
	<a href="#">Potentially Disappeared Fraction (PDF)</a>	<a href="#">Biodiversity Footprint for Financial Institutions (BFFI)</a>
	<a href="#">Mean Species Abundance (MSA)</a>	<a href="#">Biodiversity Impact Analytics (BIA-GBS)</a> ; <a href="#">Global Biodiversity Score for Financial Institutions (GBSFI)</a> ; <a href="#">Biodiversity Integrated Assessment and Computation Tool (B-INTACT)</a> ; <a href="#">Biodiversity Footprint Methodology (BFM)</a> ; <a href="#">Corporate Biodiversity Footprint (CBF)</a> ; <a href="#">Global Biodiversity Score® (GBS®)</a> ; Biodiversity Net Gain Calculator (BNGC)
Life Cycle Assessment / Product level biodiversity footprint	<a href="#">Potentially Disappeared Fraction (PDF)</a>	<a href="#">LC-IMPACT</a> , <a href="#">SCP-HAT</a> , <a href="#">Impact World+</a>
Screening and measuring supply chain	<a href="#">Species Threat Abatement and Recovery (STAR)</a> and	<a href="#">ENCORE</a>

risks and impacts	<a href="#">weighted version of MSA</a>	
	<a href="#">Potentially Disappeared Fraction (PDF)</a>	<a href="#">BioScope</a>
	<a href="#">Forest Landscape Integrity Index (FLII)</a> and <a href="#">Biodiversity Intactness Index (BII)</a>	<a href="#">Land Griffon</a>
	Lists of species of conservation concern and High Conservation Value forests	<a href="#">SPOTT</a>
	<a href="#">Potentially Disappeared Fraction (PDF)</a>	<a href="#">ReCiPe3</a>
	Tree cover change	<a href="#">GFW Pro</a>
	Various water related metrics included	<a href="#">WWF Water Risk Filter</a>
	Uses MSA and other metrics	<a href="#">WWF Biodiversity Risk Filter</a>
	Uses PDF and Species-ha metrics	<a href="#">Commodity Footprints</a>
Setting targets for nature	<a href="#">Natural Lands Map</a>	<a href="#">The SBTN land targets guidance</a>
	<a href="#">Species Threat Abatement and Recovery (STAR)</a>	
Assessing business	<a href="#">Biodiversity Intactness Index (BII)</a>	<a href="#">Integrated Biodiversity Assessment Tool (IBAT)</a>

dependencies on nature		
	Range rarity	<a href="#">ENCORE</a>
	Aggregated index of water security, timber provision, food provision, habitat intactness, pollination, soil fertility, water quality, regulation of air quality & local climate, erosion control and coastal protection	<a href="#">Biodiversity and Ecosystem Services (BES) Index</a>
Measuring the value of ecosystem services	Spatial and in some cases temporal distribution of ecosystem service layers	<a href="#">Integrated Valuation of Ecosystem Services and Tradeoffs (InVEST)</a>
	Spatial and in some cases temporal distribution of ecosystem service layers	<a href="#">Co\$ting Nature</a>
	Static Ecosystem Service maps	<a href="#">Global Modeling of Nature's Contribution to People</a>
	Ecosystem Integrity score (across 7 ecosystem service categories)	<a href="#">Ecosystem Services Identification &amp; Inventory (ESII)</a>

1080 **Table S6:** Selected examples of metrics measuring different aspects of natural  
 1081 capital and ecosystem services within the framework of genes, species, ecosystems  
 1082 and multidimensional metrics. Example papers and tools are provided according to  
 1083 the expertise of the authors, supplemented by Des Roches et al. Major categories of  
 1084 natural capital adapted from Leach et al.  
 1085

<b>Natural Capital type</b>	<b>Example ecosystem services</b>	<b>Example paper</b>	<b>Metric presented (Genes=G, Species=S, Ecosystems = E)</b>
Soils and Sediments	Soil quality	Beillouin et al. (2021) Barrios et al. (2007) Baragaoui et al. (2021)	Soil biota diversity (S) Fungal leaf litter decomposition (G)
Water	Water quality	Duarte et al. (2019) Vaughn (2018) Seena et al. (2023) Thomaz (2023) <a href="#">Waterworld</a> (Mulligan 2009, 2013, 2022)	Water quality metrics (turbidity, pollutant loads, clarity) (E)
	Water availability	<a href="#">Aqueduct</a> (Kuzma et al. 2023) <a href="#">Waterworld</a>	Water stress (E)
Forests	Biodiversity habitats	Zytynska et al. (2011)	Within-species genetic variation (G)
Grasslands	Biodiversity habitats	Sollenberger et al. (2019) Bengtsson et al. (2019)	Pollinator habitat (S)

Genetic resources, and plant, animal, fungal, and algal species	Timber	Felipe-Lucia et al. (2018); Swenk et al. (2012)	Timber volumes in trade (S)
	Nontimber forest products	Chair et al. (2011) <i>Charcoal</i> : Schaafsma et al. 2014 <i>Building materials</i> : Schaafsma et al. 2012	Charcoal and building materials volumes and values in trade (S,E)
	Medicinal plants	<i>Case studies</i> : Caballero-Serrano et al. (2019); Perinchery (2020); Sucholas et al. (2017)	Medicinal plants volumes and values in trade (S)
	Wildlife trade / trophy hunting	Traits for hunting selection literature	Volumes, values, numbers of wildlife products in trade (S)
	Wildmeat (Coad et al. 2019; Ingram et al. 2021)	Selection traits literature	Wildmeat species volumes and values in trade (S)
	Domestic species	FAO livestock diversity	Domesticated animal numbers, volumes and values in trade (G)
Multidimensional ecosystem bundles	Bundles of services from wild biodiversity	<a href="#">Co\$ting Nature</a> ; Willcock et al. 2019, 2023; Provost et al. 2022	Ecosystem bundles amounts and values available or delivered to people (S,E)
